Prairie Pothole Region

An expansive, deglaciated agriculturally-dominated, wetland-heavy region of southern Canada and north-central Midwestern US.

Enclosed depressions that often retain water for some portion of the year

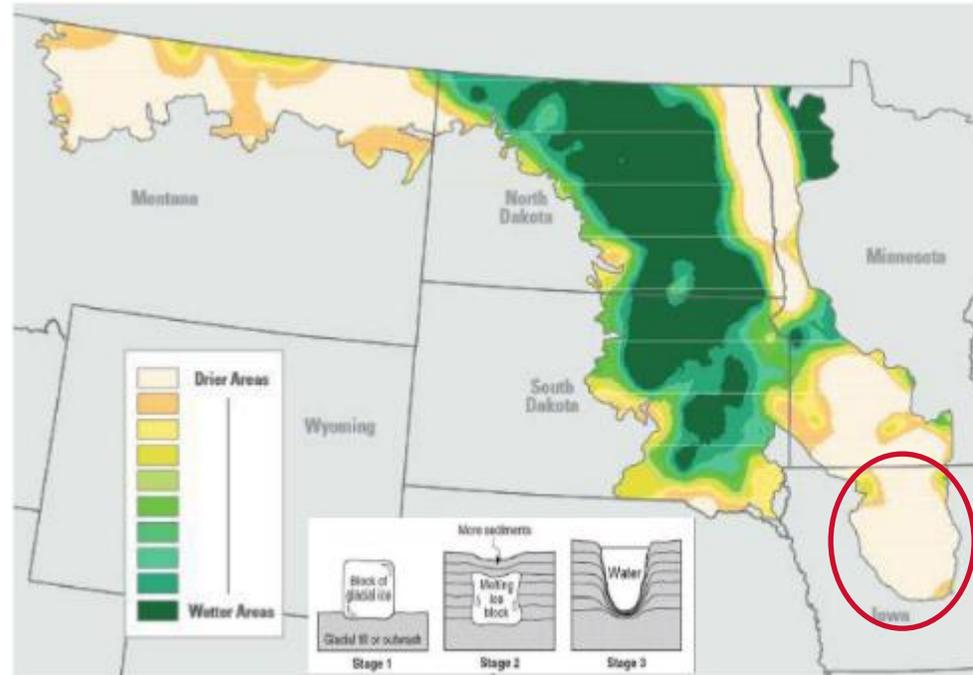

*Stevens and Salman, 2015.
Wade, 2013.*

Prairie Pothole Region

An expansive, deglaciated agriculturally-dominated, wetland-heavy region of southern Canada and north-central Midwestern US.

Enclosed depressions that often retain water for some portion of the year

*Stevens and Salman, 2015.
Wade, 2013.*

Hydrology Basics

- 44% of Des Moines Lobe drains to potholes
- Ponding causes crop loss
 - 3-5 days of ponded water drowns young row crops
- Inflows: rainfall, runoff, and interflow
 - Rising water table appears to have little influence
- Outflows: evapotranspiration, overflow, surface drainage, and infiltration

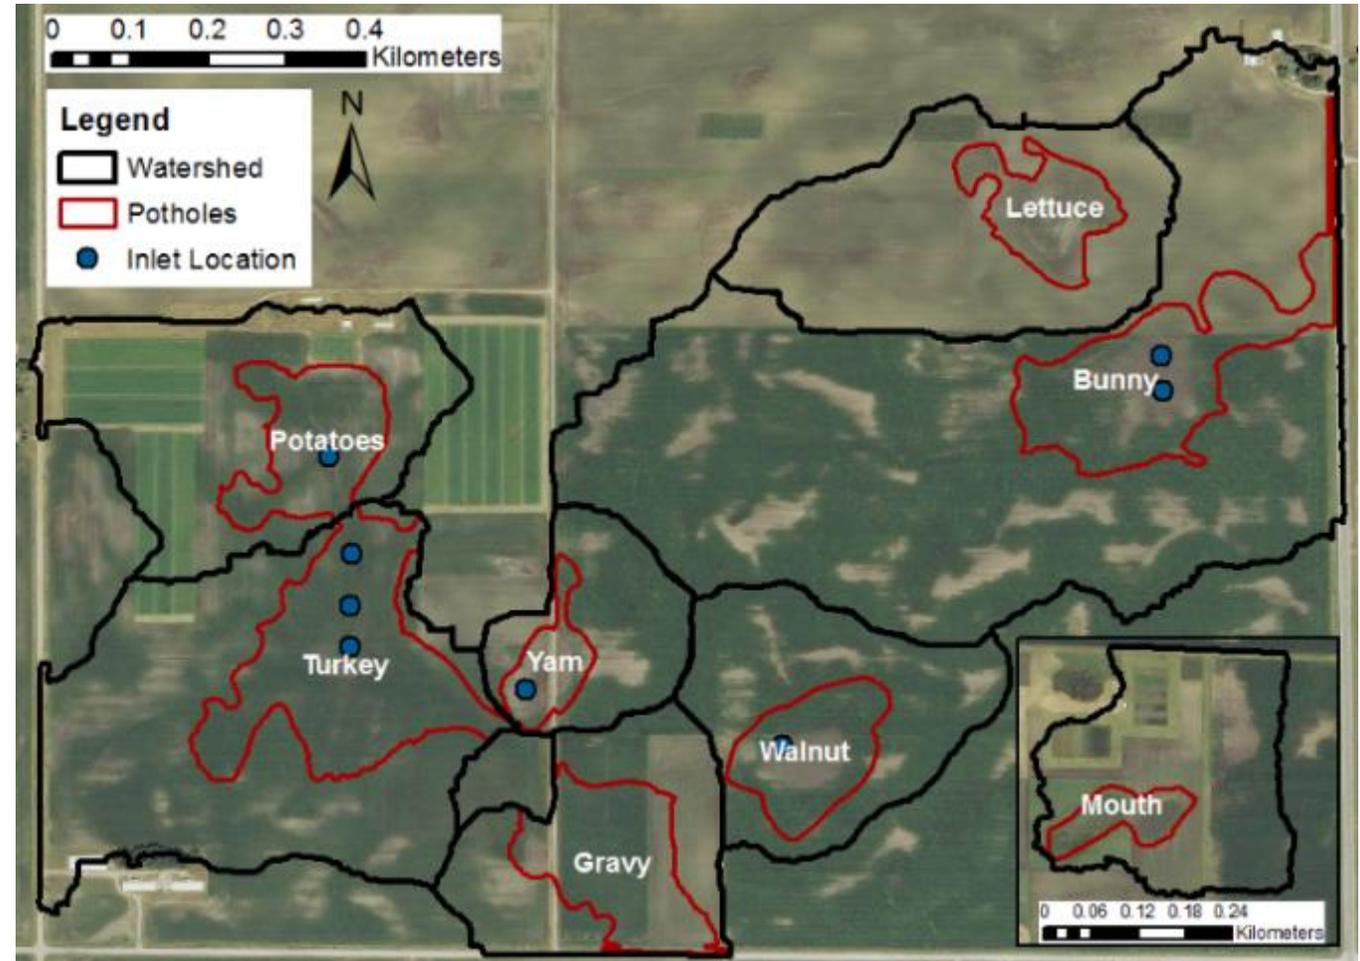

Subsurface Drainage

- 95-99% of potholes in Iowa are drained
- Earlier work on water balance
 - Did not estimate infiltration
 - Did not account for any “diminished capacity” of the drainage system (partial clogging; back-up)
 - Ignored surface risers

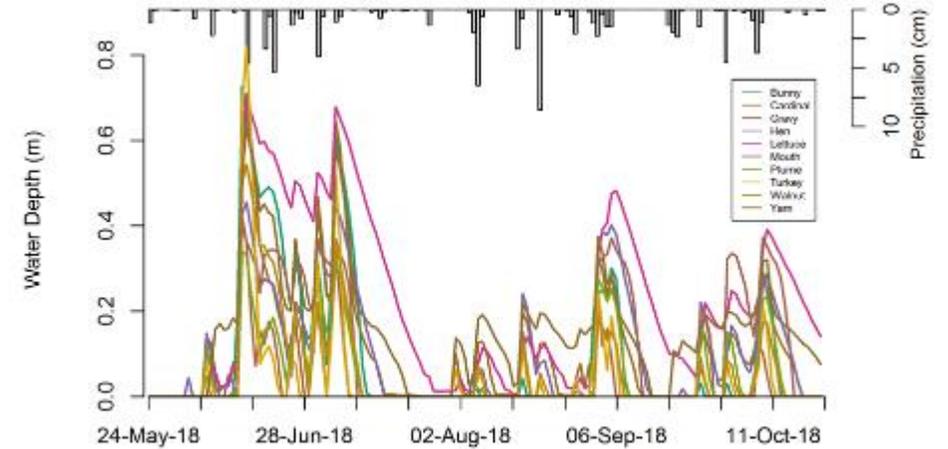

Study Site (2016-present)

- Two+ HUC-12 Watersheds
- Varying levels of subsurface drainage (none to intense)
- Varying levels of surface inlets (none to three)
- Seven conventional C/S management; one CRP

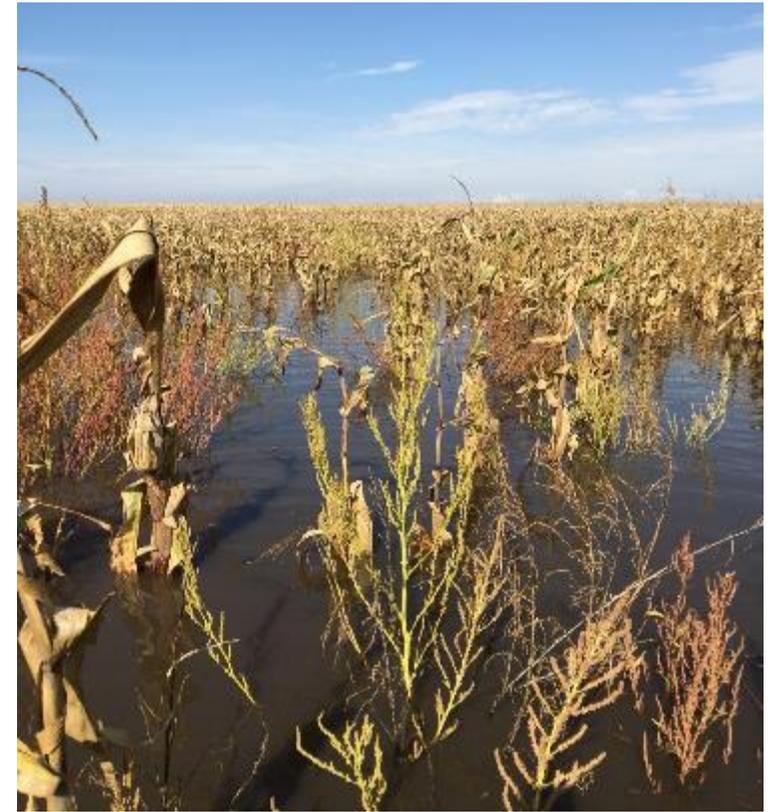

Every pothole flooded.

Pothole		Bunny	Gravy	Lettuce	Mouth	Potatoes	Turkey	Walnut	Yam
2016 (Medium)	Inundation Days	13	5	55	35	4	6	15	
	Days Monitored	173	173	173	173	173	173	173	
	Inundation Percent	8%	3%	32%	20%	2%	3%	9%	
2017 (Dry)	Inundation Days	2	0	1	11	0	2	3	48
	Days Monitored	171	171	171	171	171	171	171	171
	Inundation Percent	1%	0%	1%	6%	0%	1%	2%	28%
2018 (Wet)	Inundation Days	40	18	123	52		24	40	115
	Days Monitored	148	148	151	165		148	151	151
	Inundation Percent	27%	12%	81%	32%		16%	26%	76%

Sometimes for a long time.

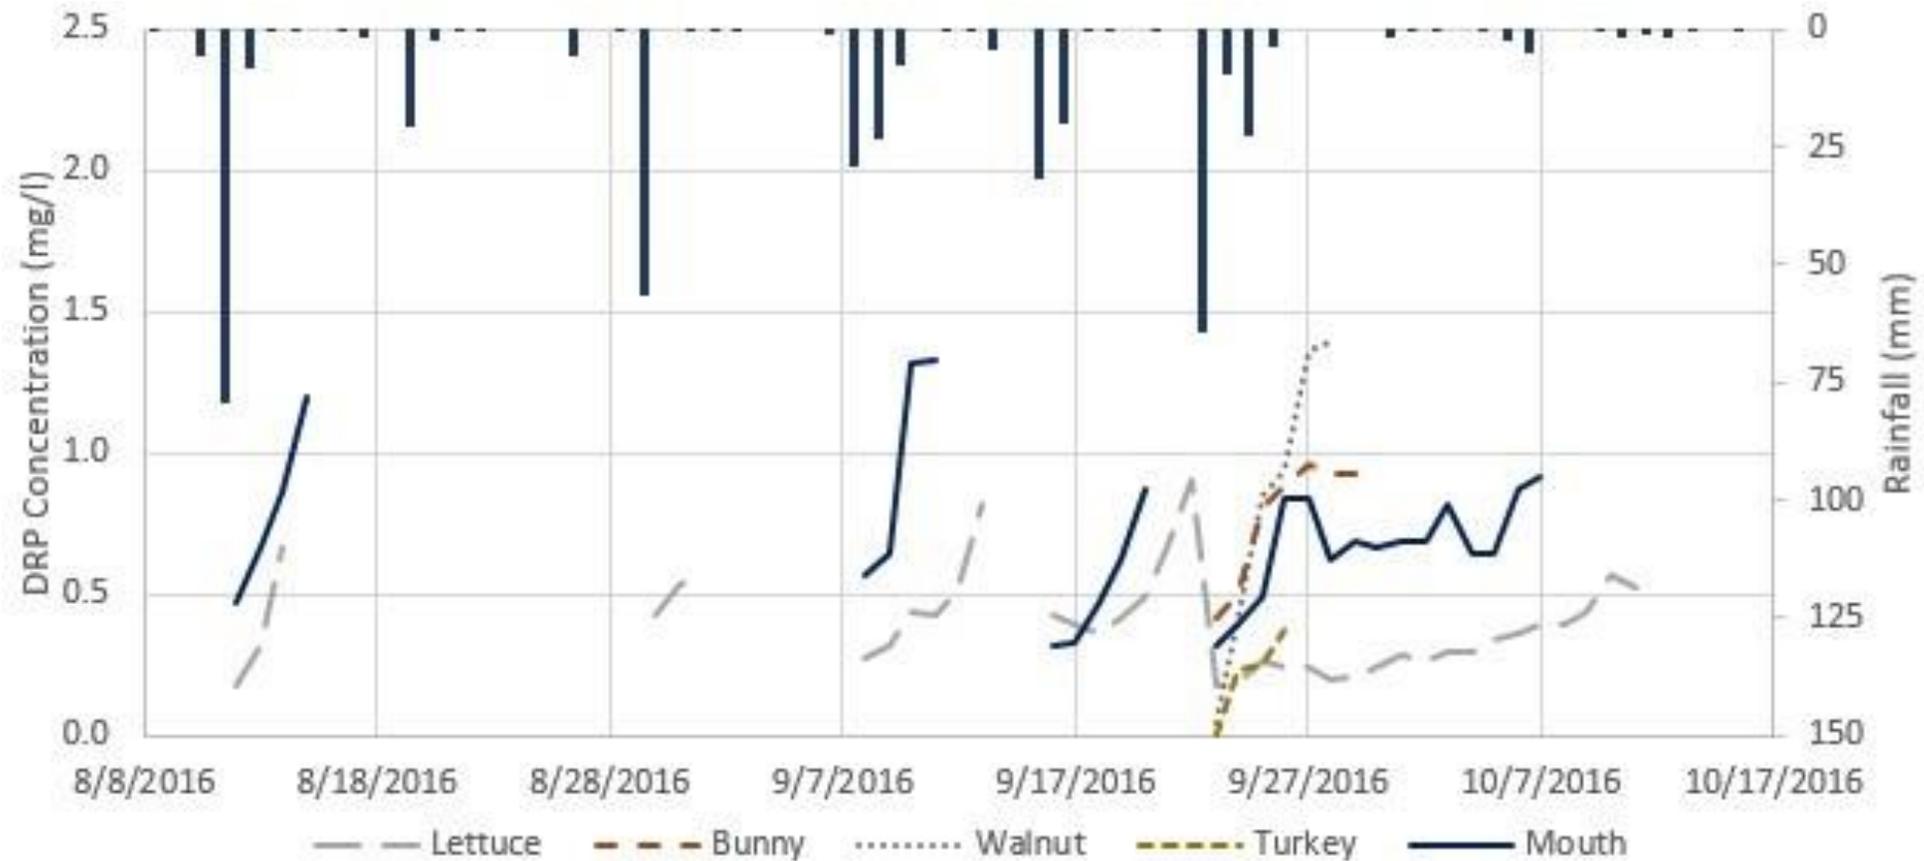

- Over half of the ponding events were 2 or less days, but ...
- Two events (both 2018) were over 50 days
- 6 of 8 potholes had at least one event of 5 or more days in two of the three years

Nitrate flushed into the potholes in early season events.

- 20 multiday events
 - Concentrations high in early season “first flush” conditions
 - Concentrations low in later-season events.
 - 17 had nitrate reduction (and 2 were non-detects throughout)

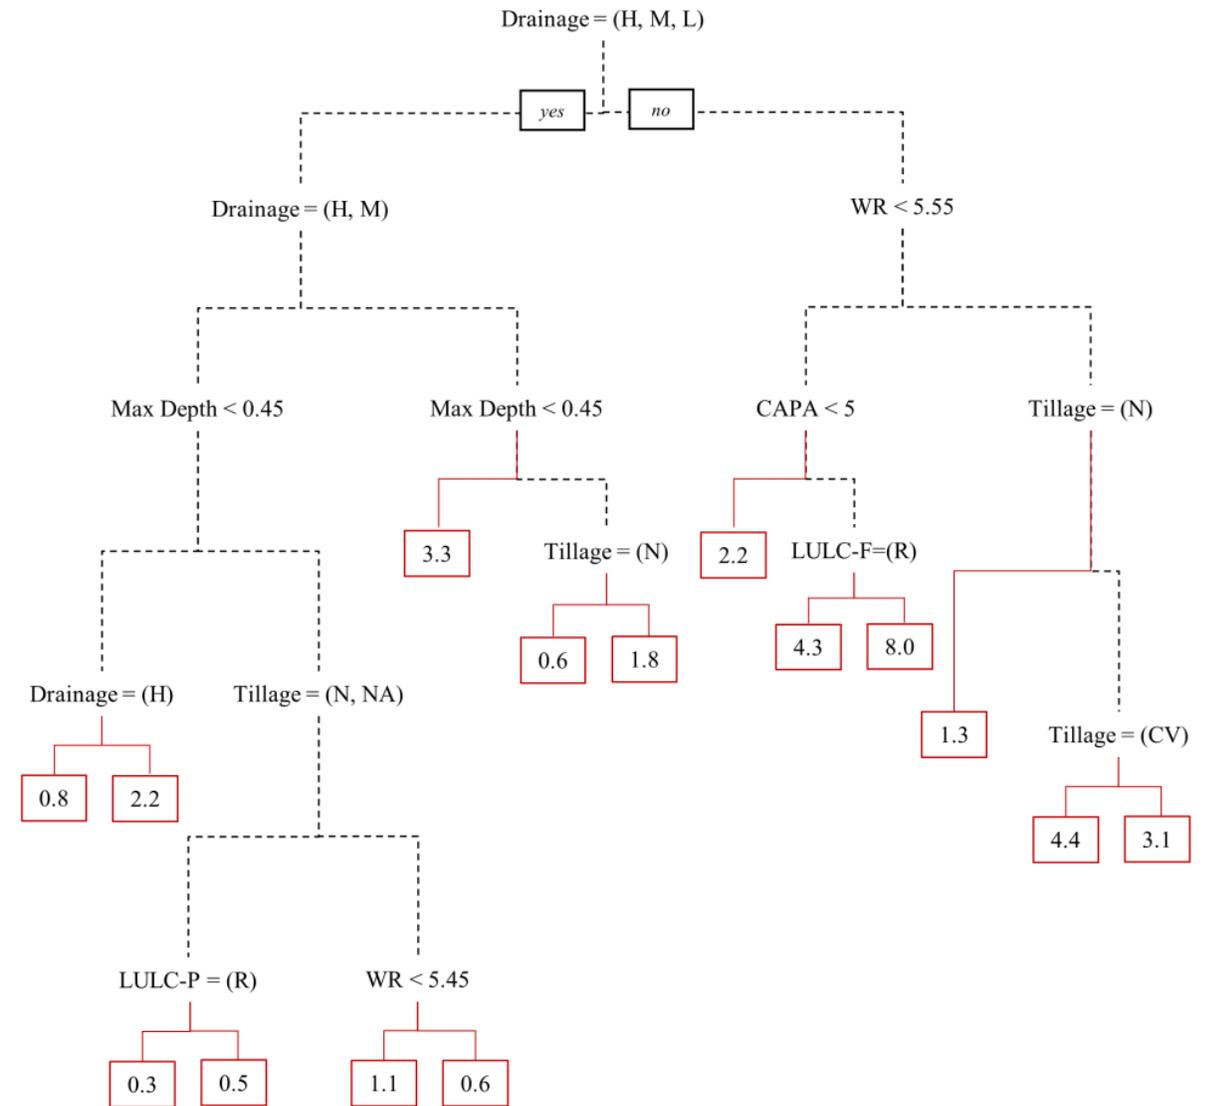

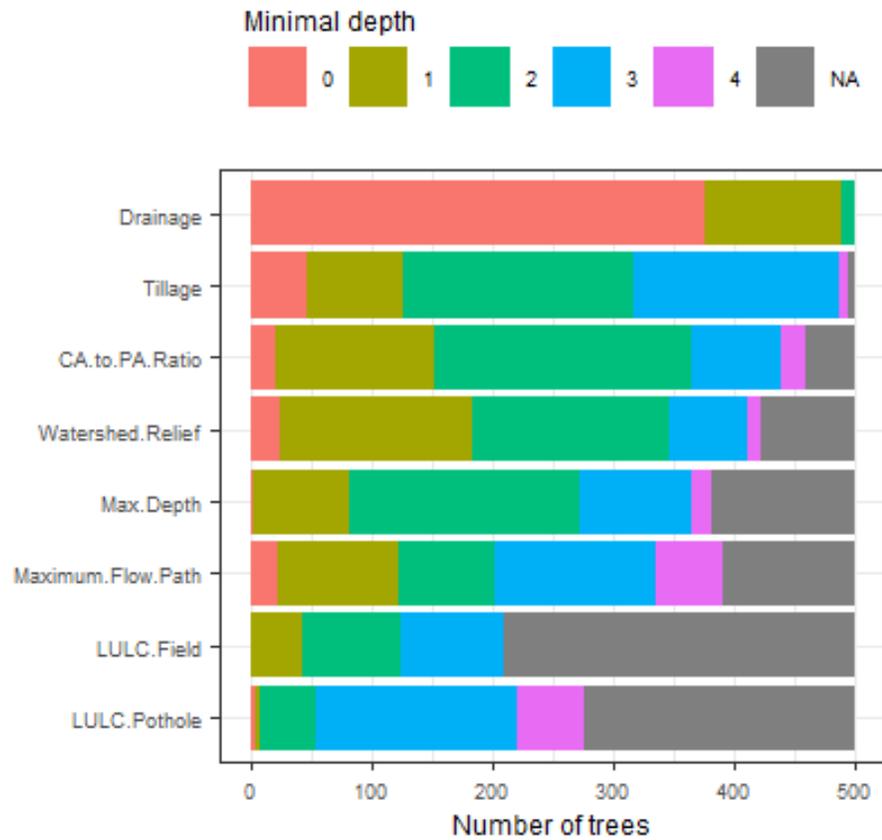

Dissolved reactive phosphorus concentration increased over the course of an inundation event

Modeling Pothole Inundation

- AnnAGNPS models for six potholes to generate longer-term dataset (25 years) of daily inundation estimates
- Look at changes to
 - Drainage intensity (no subsurface drainage, subsurface drainage with and without surface inlets)
 - Land cover in the pothole (cropped or retired)
 - Land cover in the microwatershed (cropped or retired)
- Develop a “risk metric” that incorporates probability of drowning the crop, of being too wet to plant or harvest

Building a Risk Assessment Tool

1. Enter your County

Story

2. Enter a personal field ID

MyFieldID

3. What is the land use of the pothole?

- Corn-Soybean Rotation
 Perennial Cover (Conservation Reserve, Grassed, etc.)

4. What is the land use of the field?

- Corn-Soybean Rotation
 Perennial Cover (Conservation Reserve, Grassed, etc.)

5. Specify existing drainage

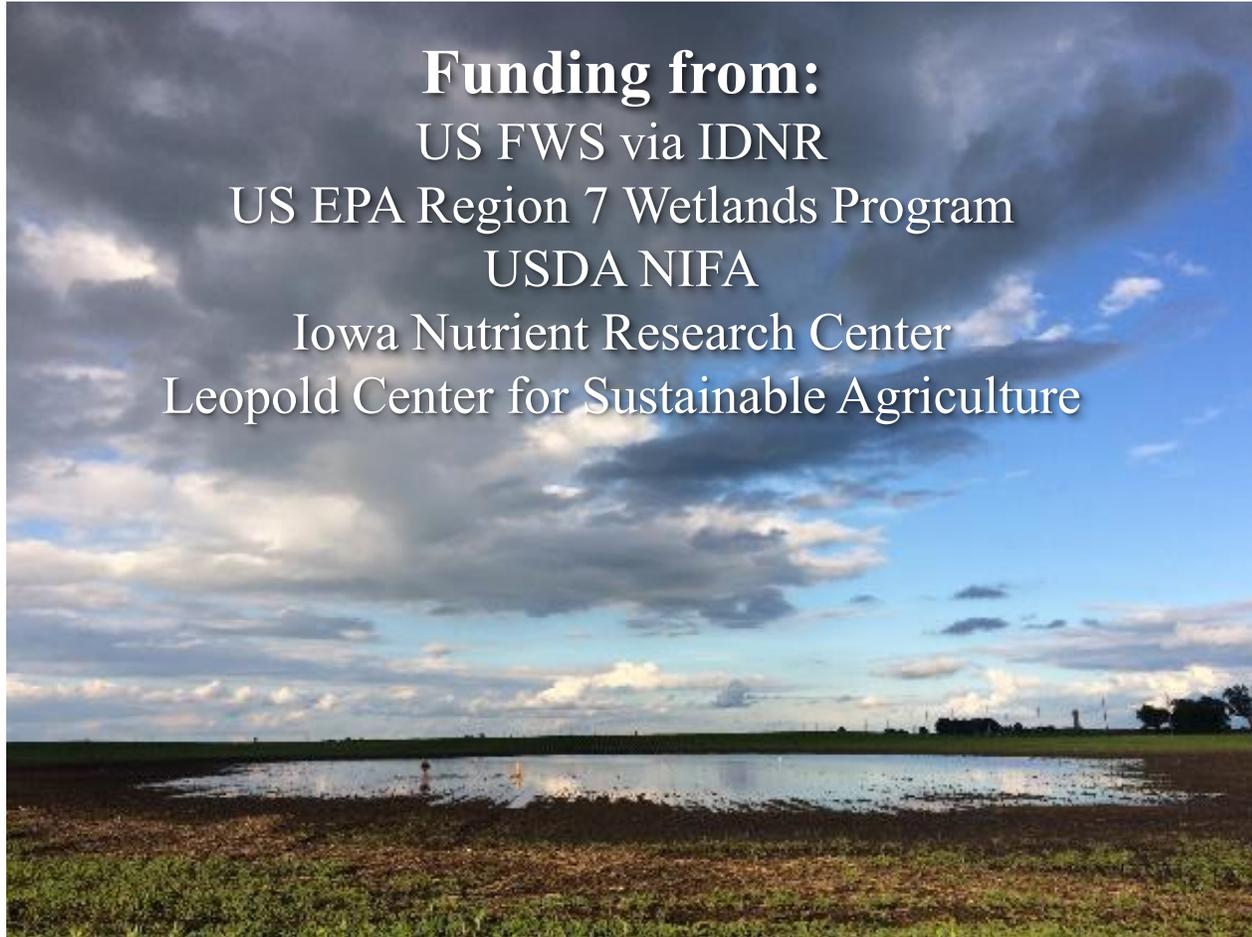

No drainage

6. Specify current tillage

Conventional

7. Estimate the maximum land extent of the pothole (acres)**8. Estimate the contributing flow area to the pothole (acres)****9. Estimate the maximum flooding depth of the pothole (feet)**
