## **Funding**

ADF&G, BLM, NPS, and EPA

## **Field Data**

Numerous ecologists and technicians for over 30 years!

# Outline

1. Why change a good thing?
2. Automated polygon delineation (image segmentation + aggregation)
3. Mapping wetlands directly
4. Mapping wetland components
5. Conclusion and questions

# Why change a good thing?

*Manual delineation* is a “tried and true” method to produce reliable results given a knowledgeable analyst.

# Why change a good thing?

*Manual delineation* is a “tried and true” method to produce reliable results given a knowledgeable analyst.

*Automated methods* offer:

1. Statistically robust accuracy assessment.
2. Consistency at large extents.
3. Integration of multi-parameter wetland attributes.
4. Repeatability for updates and alterations.
5. Cost efficiency for large regions.

# Why change a good thing?

*Manual delineation* is a “tried and true” method to produce reliable results given a knowledgeable analyst.

*Automated methods* offer:

1. Statistically robust accuracy assessment.
2. Consistency at large extents.
3. Integration of multi-parameter wetland attributes.
4. Repeatability for updates and alterations.
5. Cost efficiency for large regions.

**Goal:** demonstrate ideas to integrate *manual delineation* and *automated methods* while retaining strengths

# Definitions and clarifications

*Wetlands*: defined according to Cowardin classification

*1-parameter wetlands*: defined based solely on dominance of hydrophytic vegetation

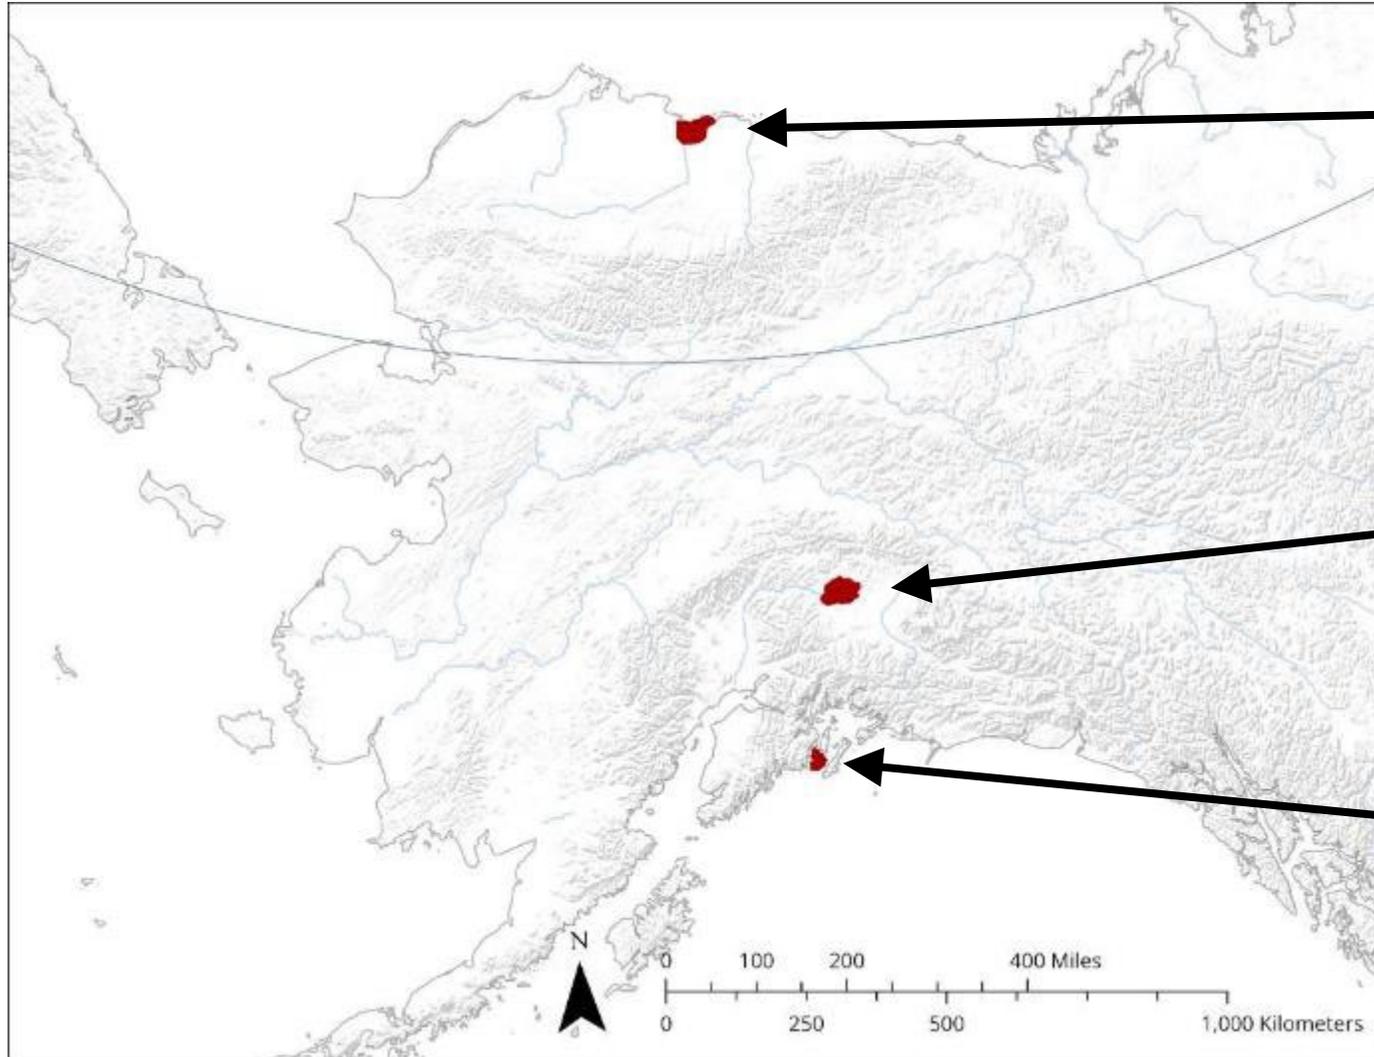

*3-parameter wetlands*: defined based on

- dominance of hydrophytic vegetation
- substrate is predominantly undrained hydric soil
- saturated/covered with water part of growing season

*Wetland plant communities*: defined according to U.S. National Vegetation Classification

# Definitions and clarifications

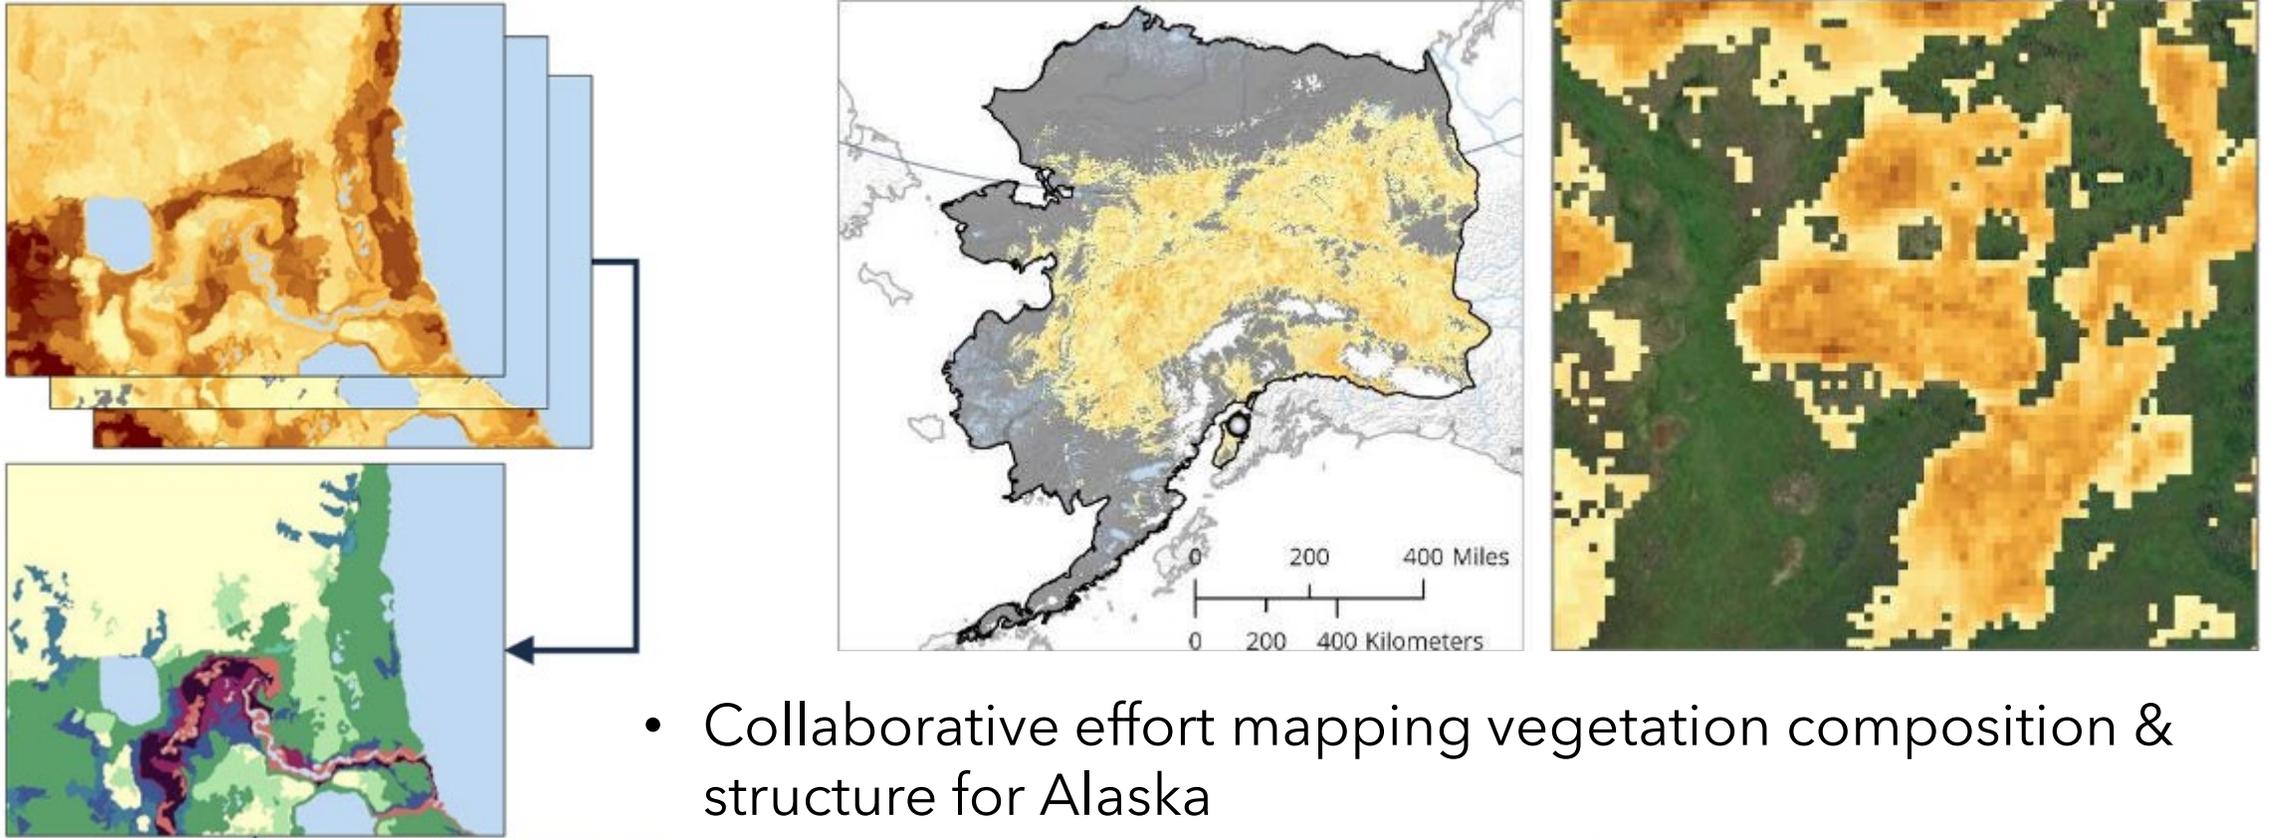

GMT-2 (Arctic)  
AKVEG pilot project

Alphabet Hills (boreal)  
AKVEG pilot project

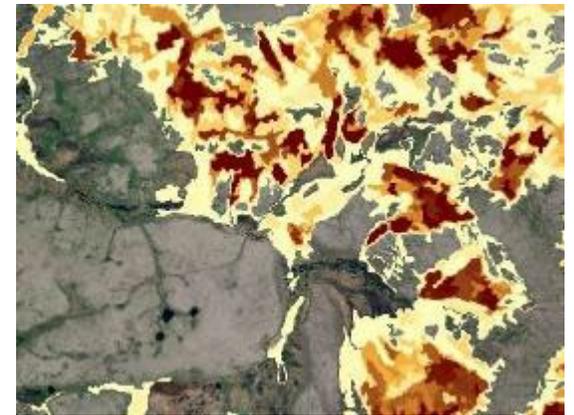

Chenega (temperate)  
*NWI preliminary results; not QC'ed*

# AKVEG Map: high ecological and spatial resolution

- Collaborative effort mapping vegetation composition & structure for Alaska
- Currently available: foliar cover of plant species, aggregates, and functional types (version 1.0)
- Nawrocki et al. 2021 & Macander et al. 2022

# AKVEG Map represents wetland plant communities (USNVC)

Break ecological complexity to manageable units.

## Two types of maps:

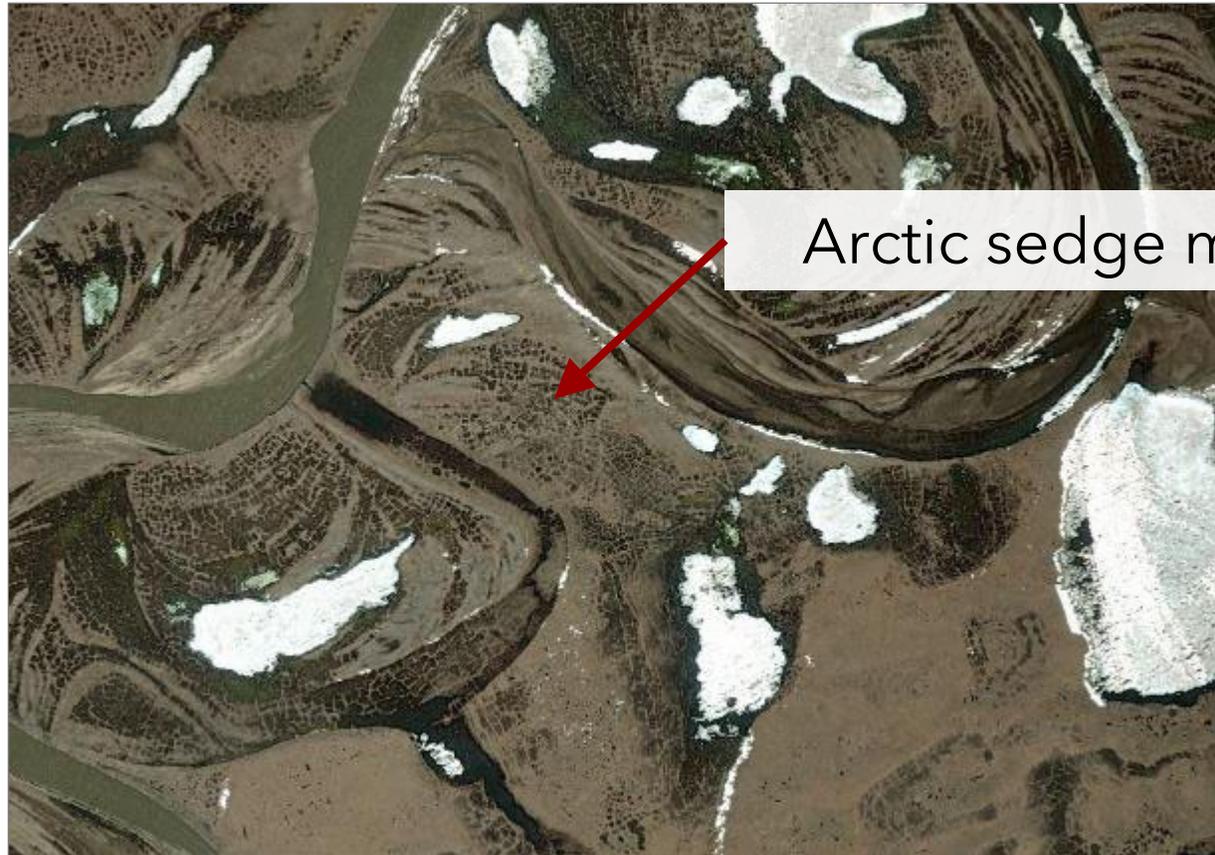

high cover

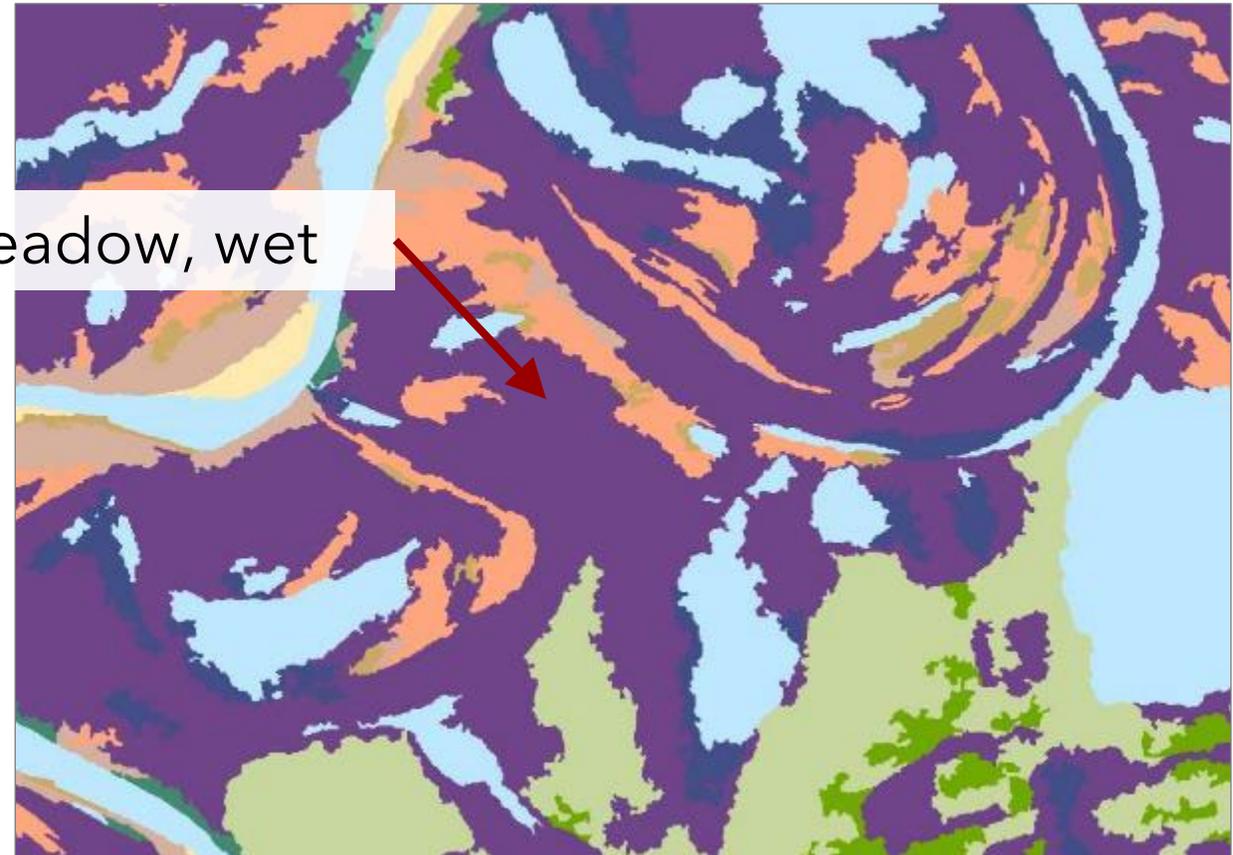

Continuous maps show "what is present" using numbers

## Two types of maps:

Categorical maps describe what the feature “looks like”

Arctic sedge meadow, wet

Existing Vegetation Types (USNVC Alliances)

# Semi-automated workflow

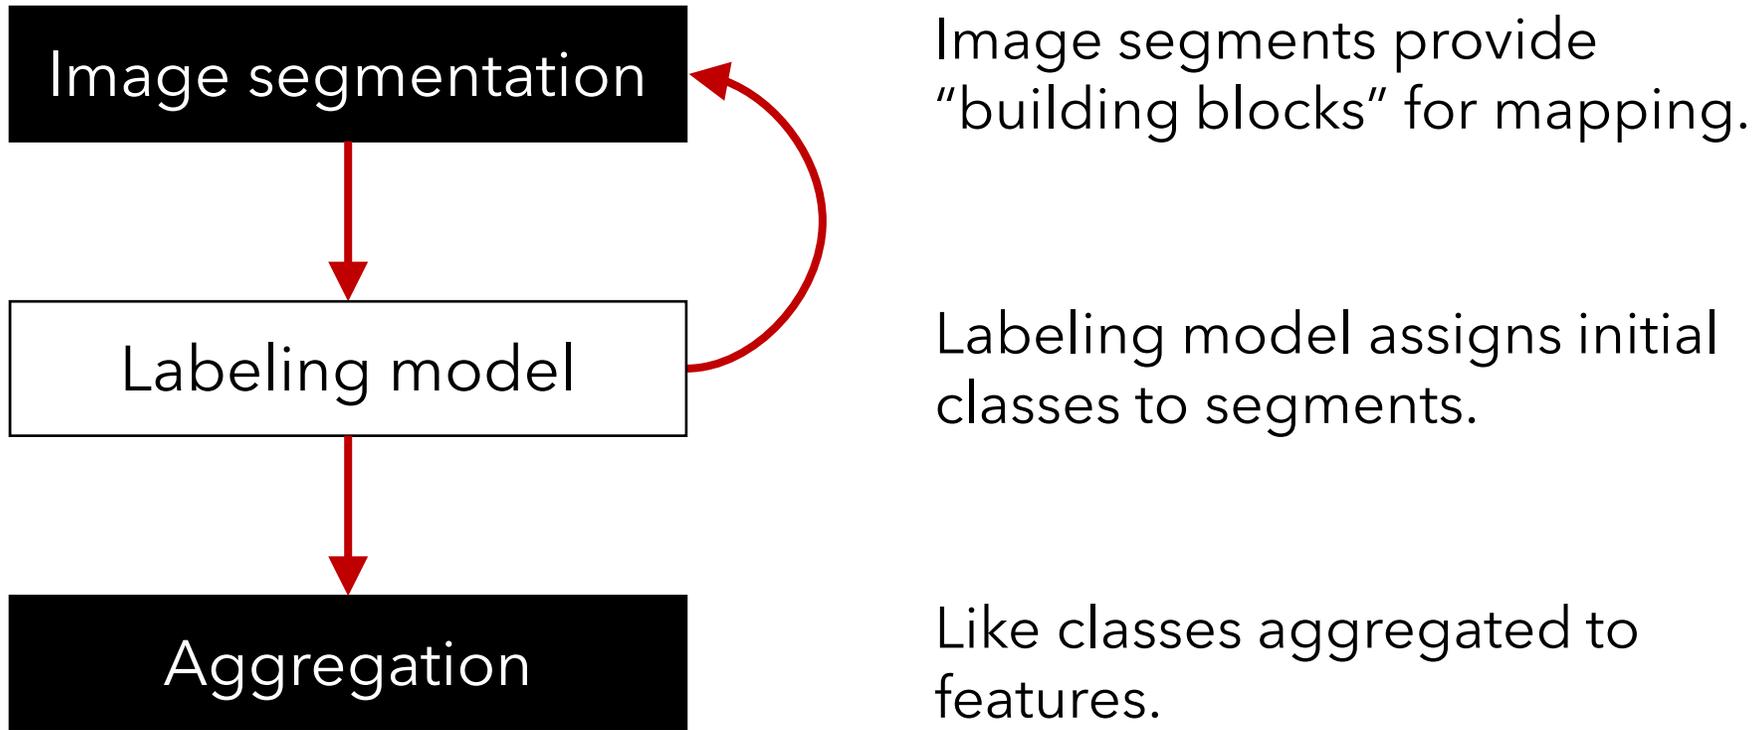

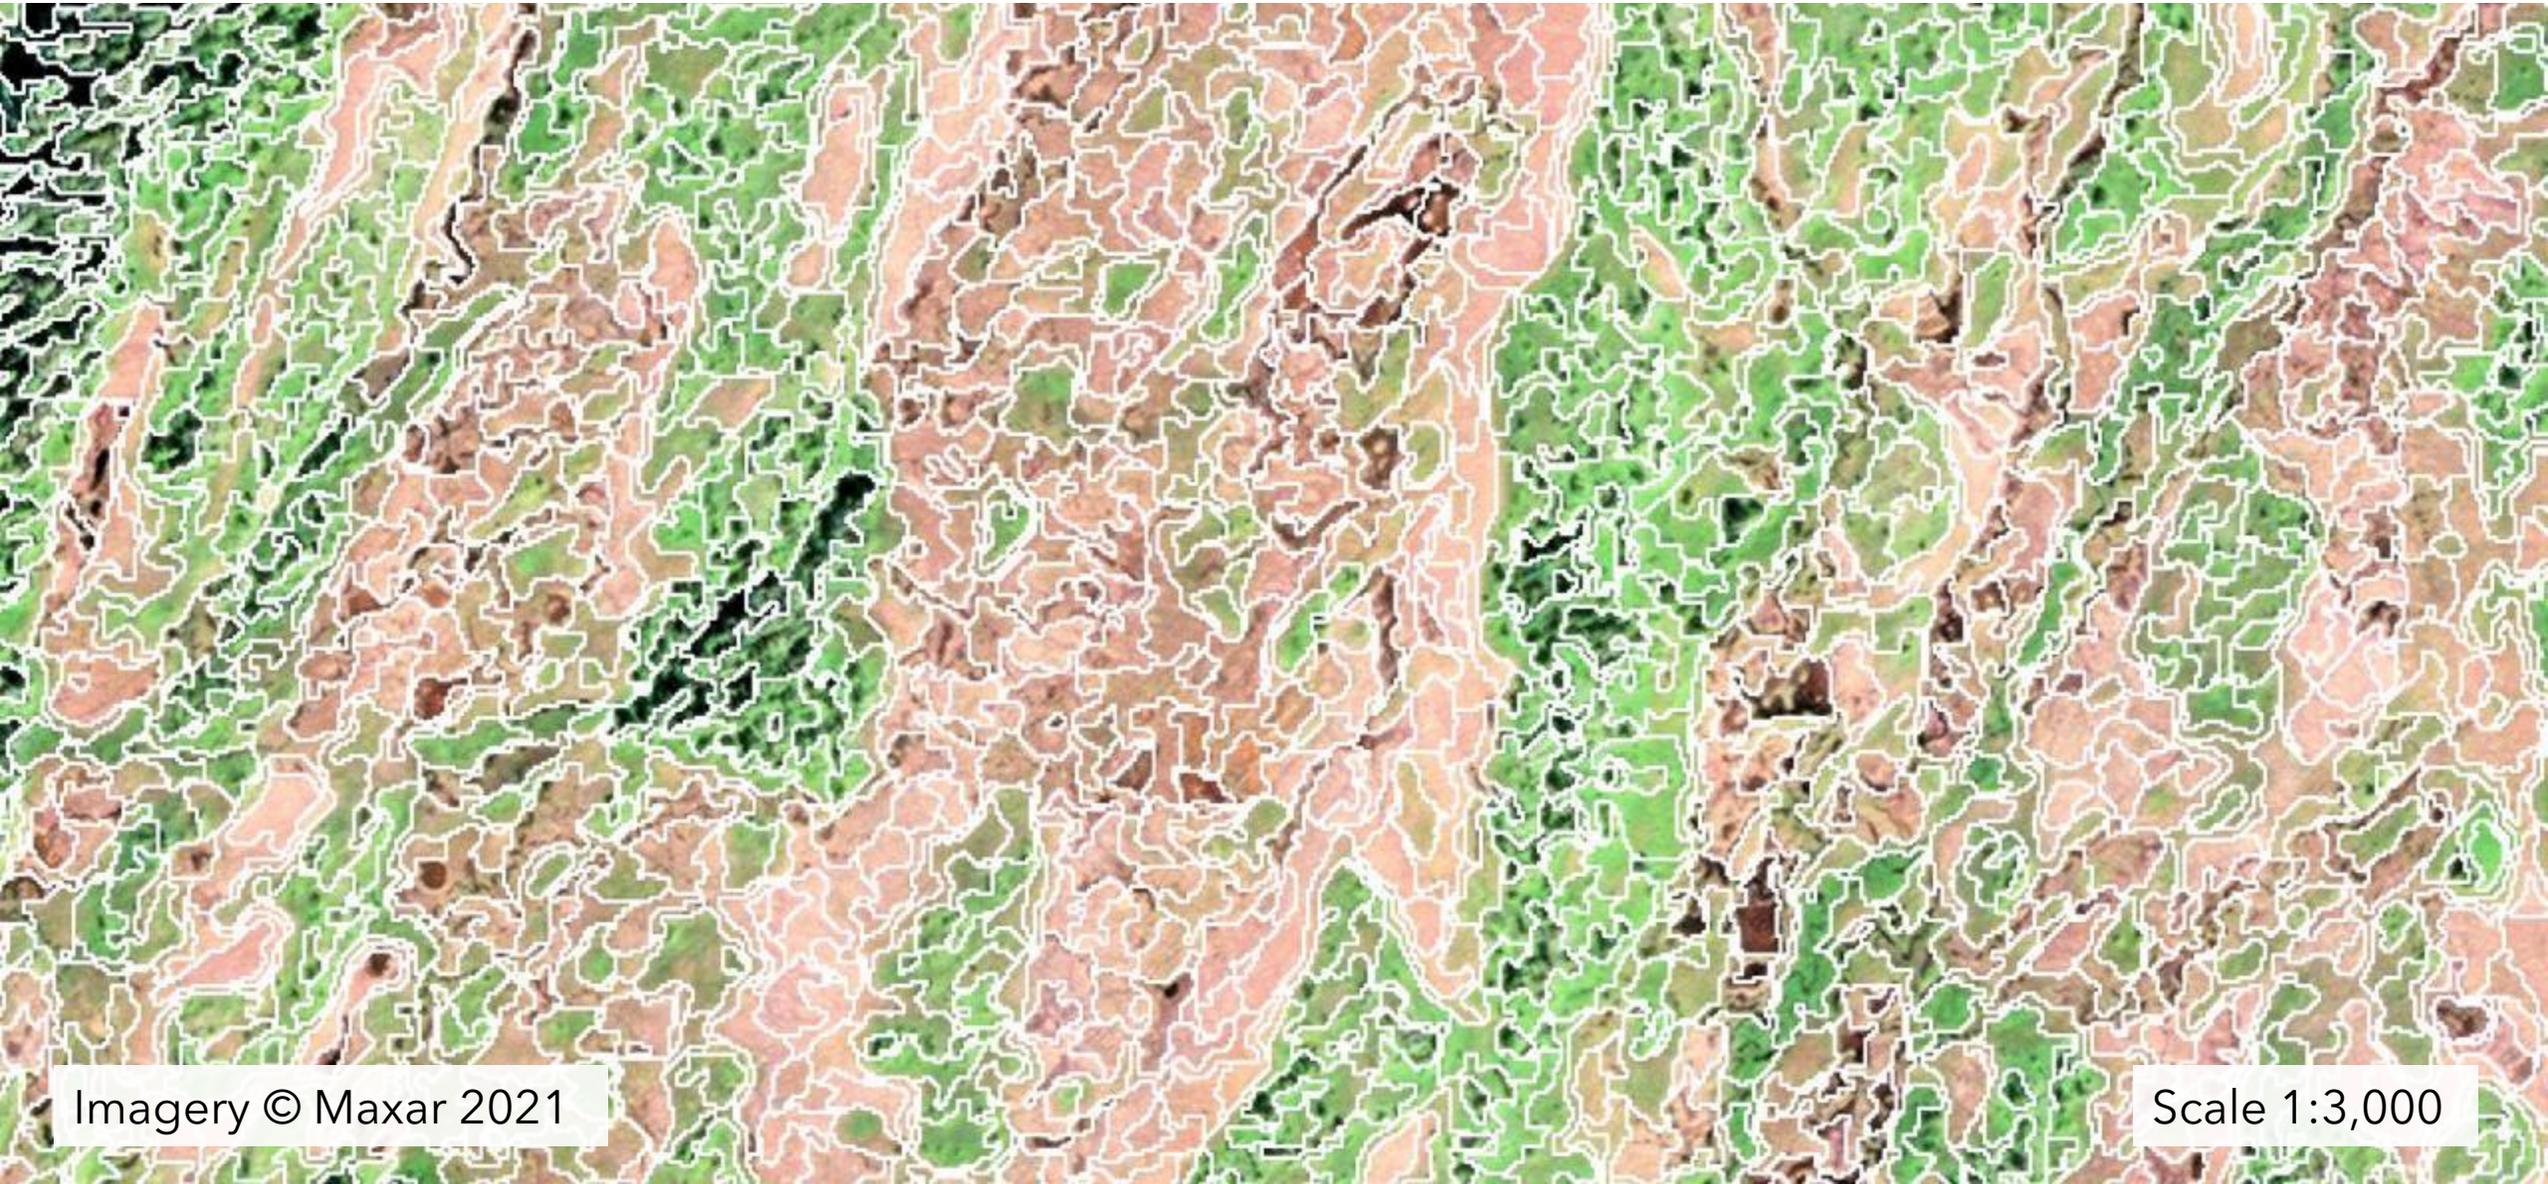

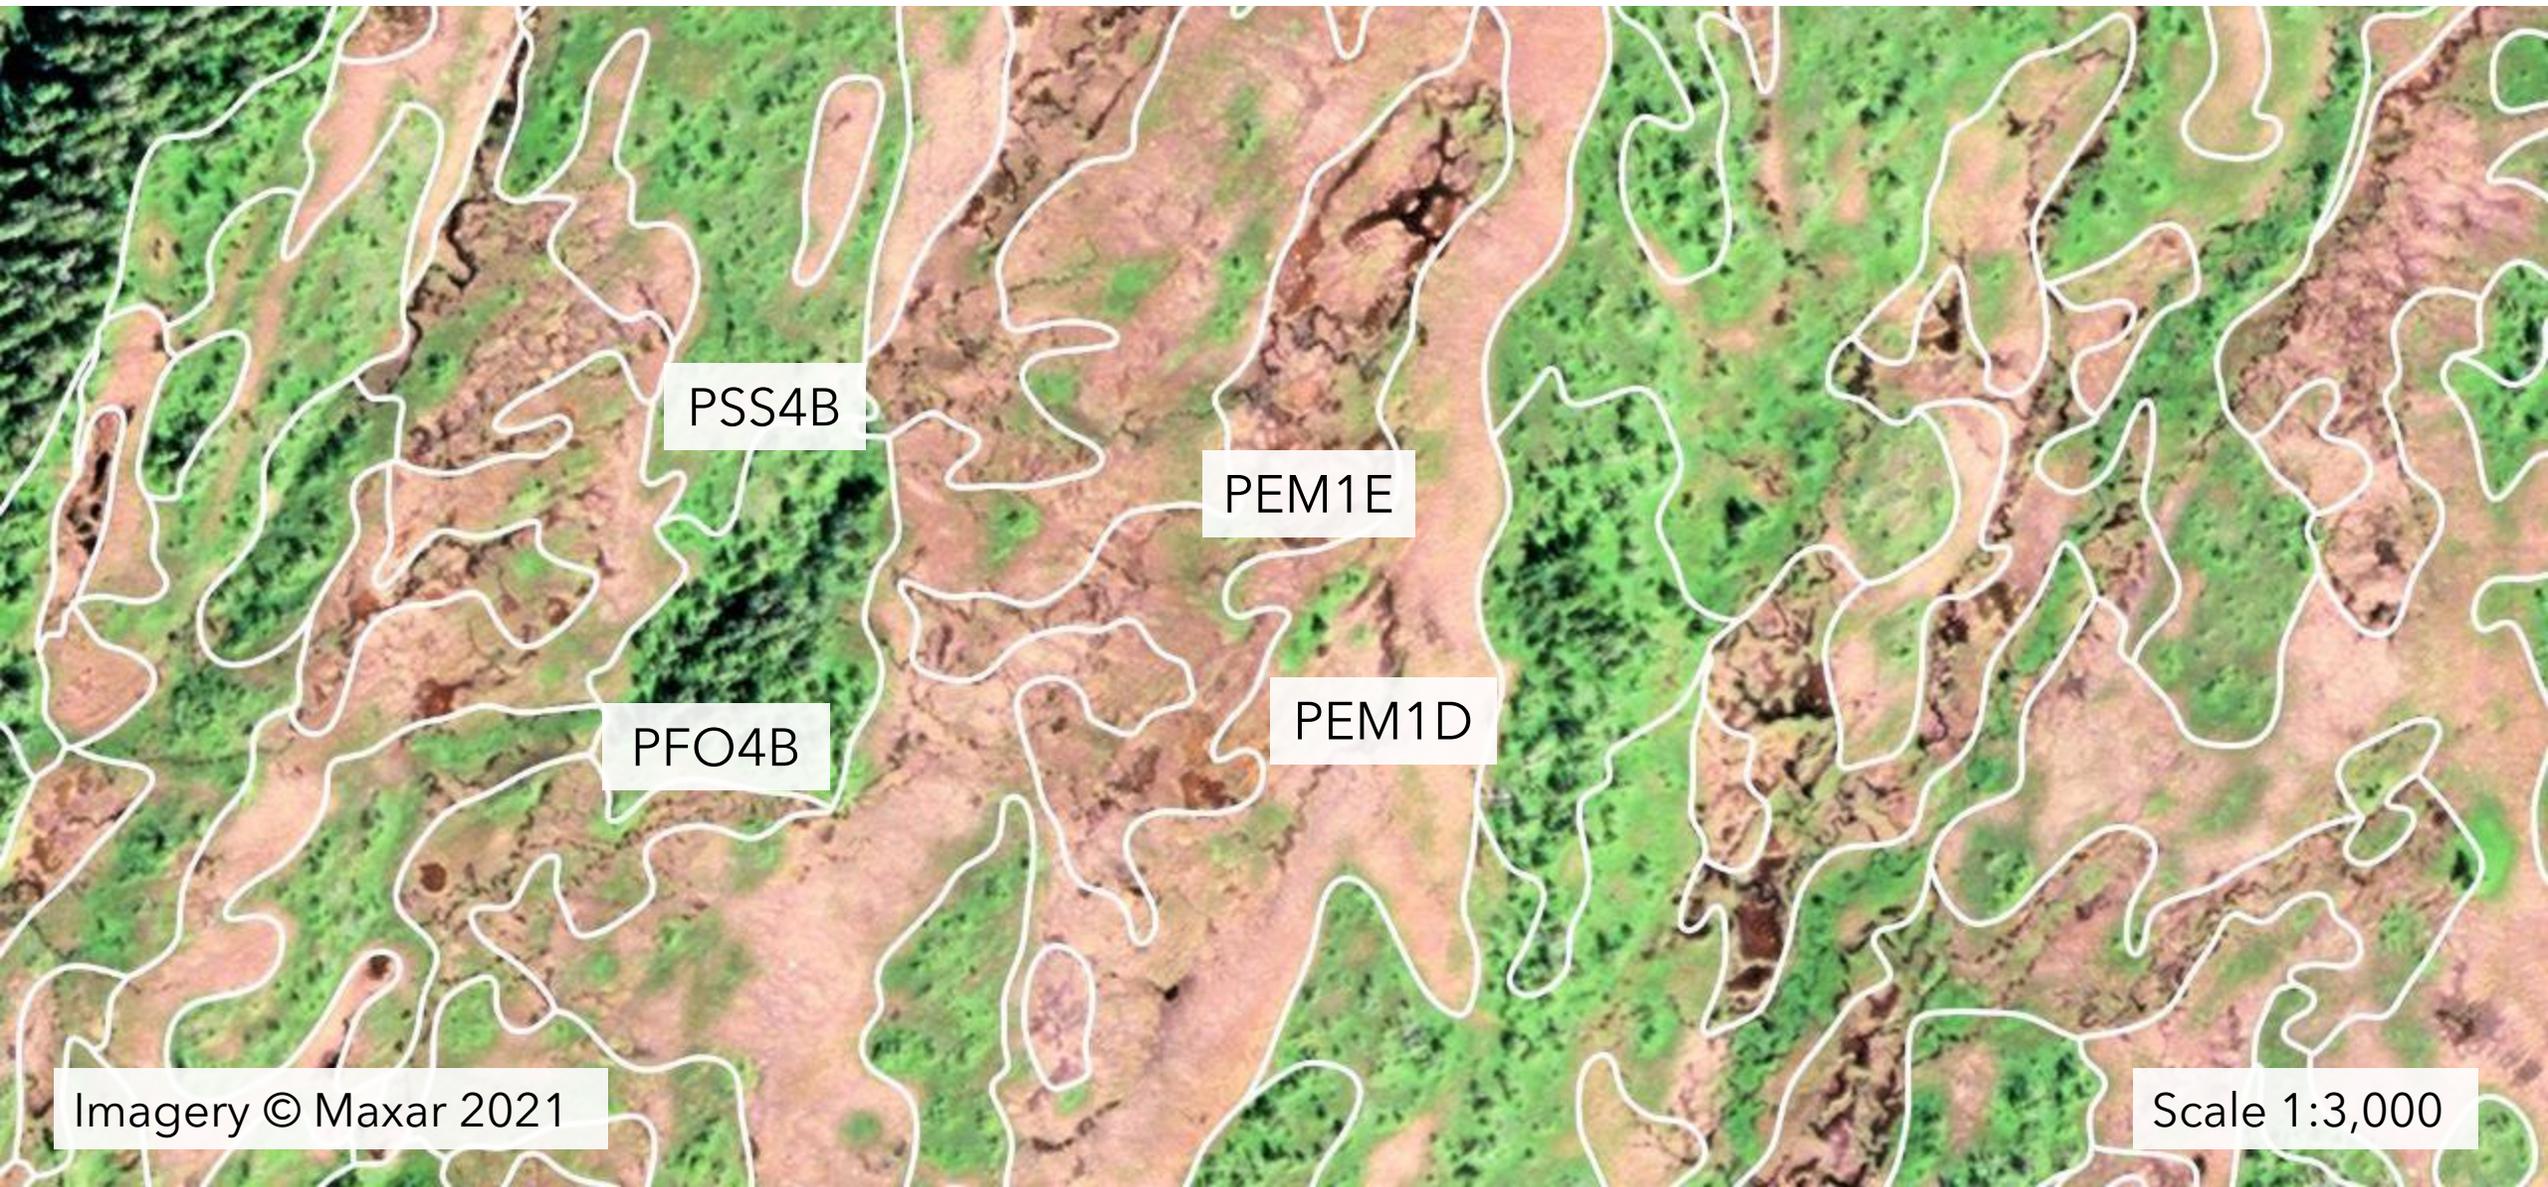

Image segments developed from high-res imagery

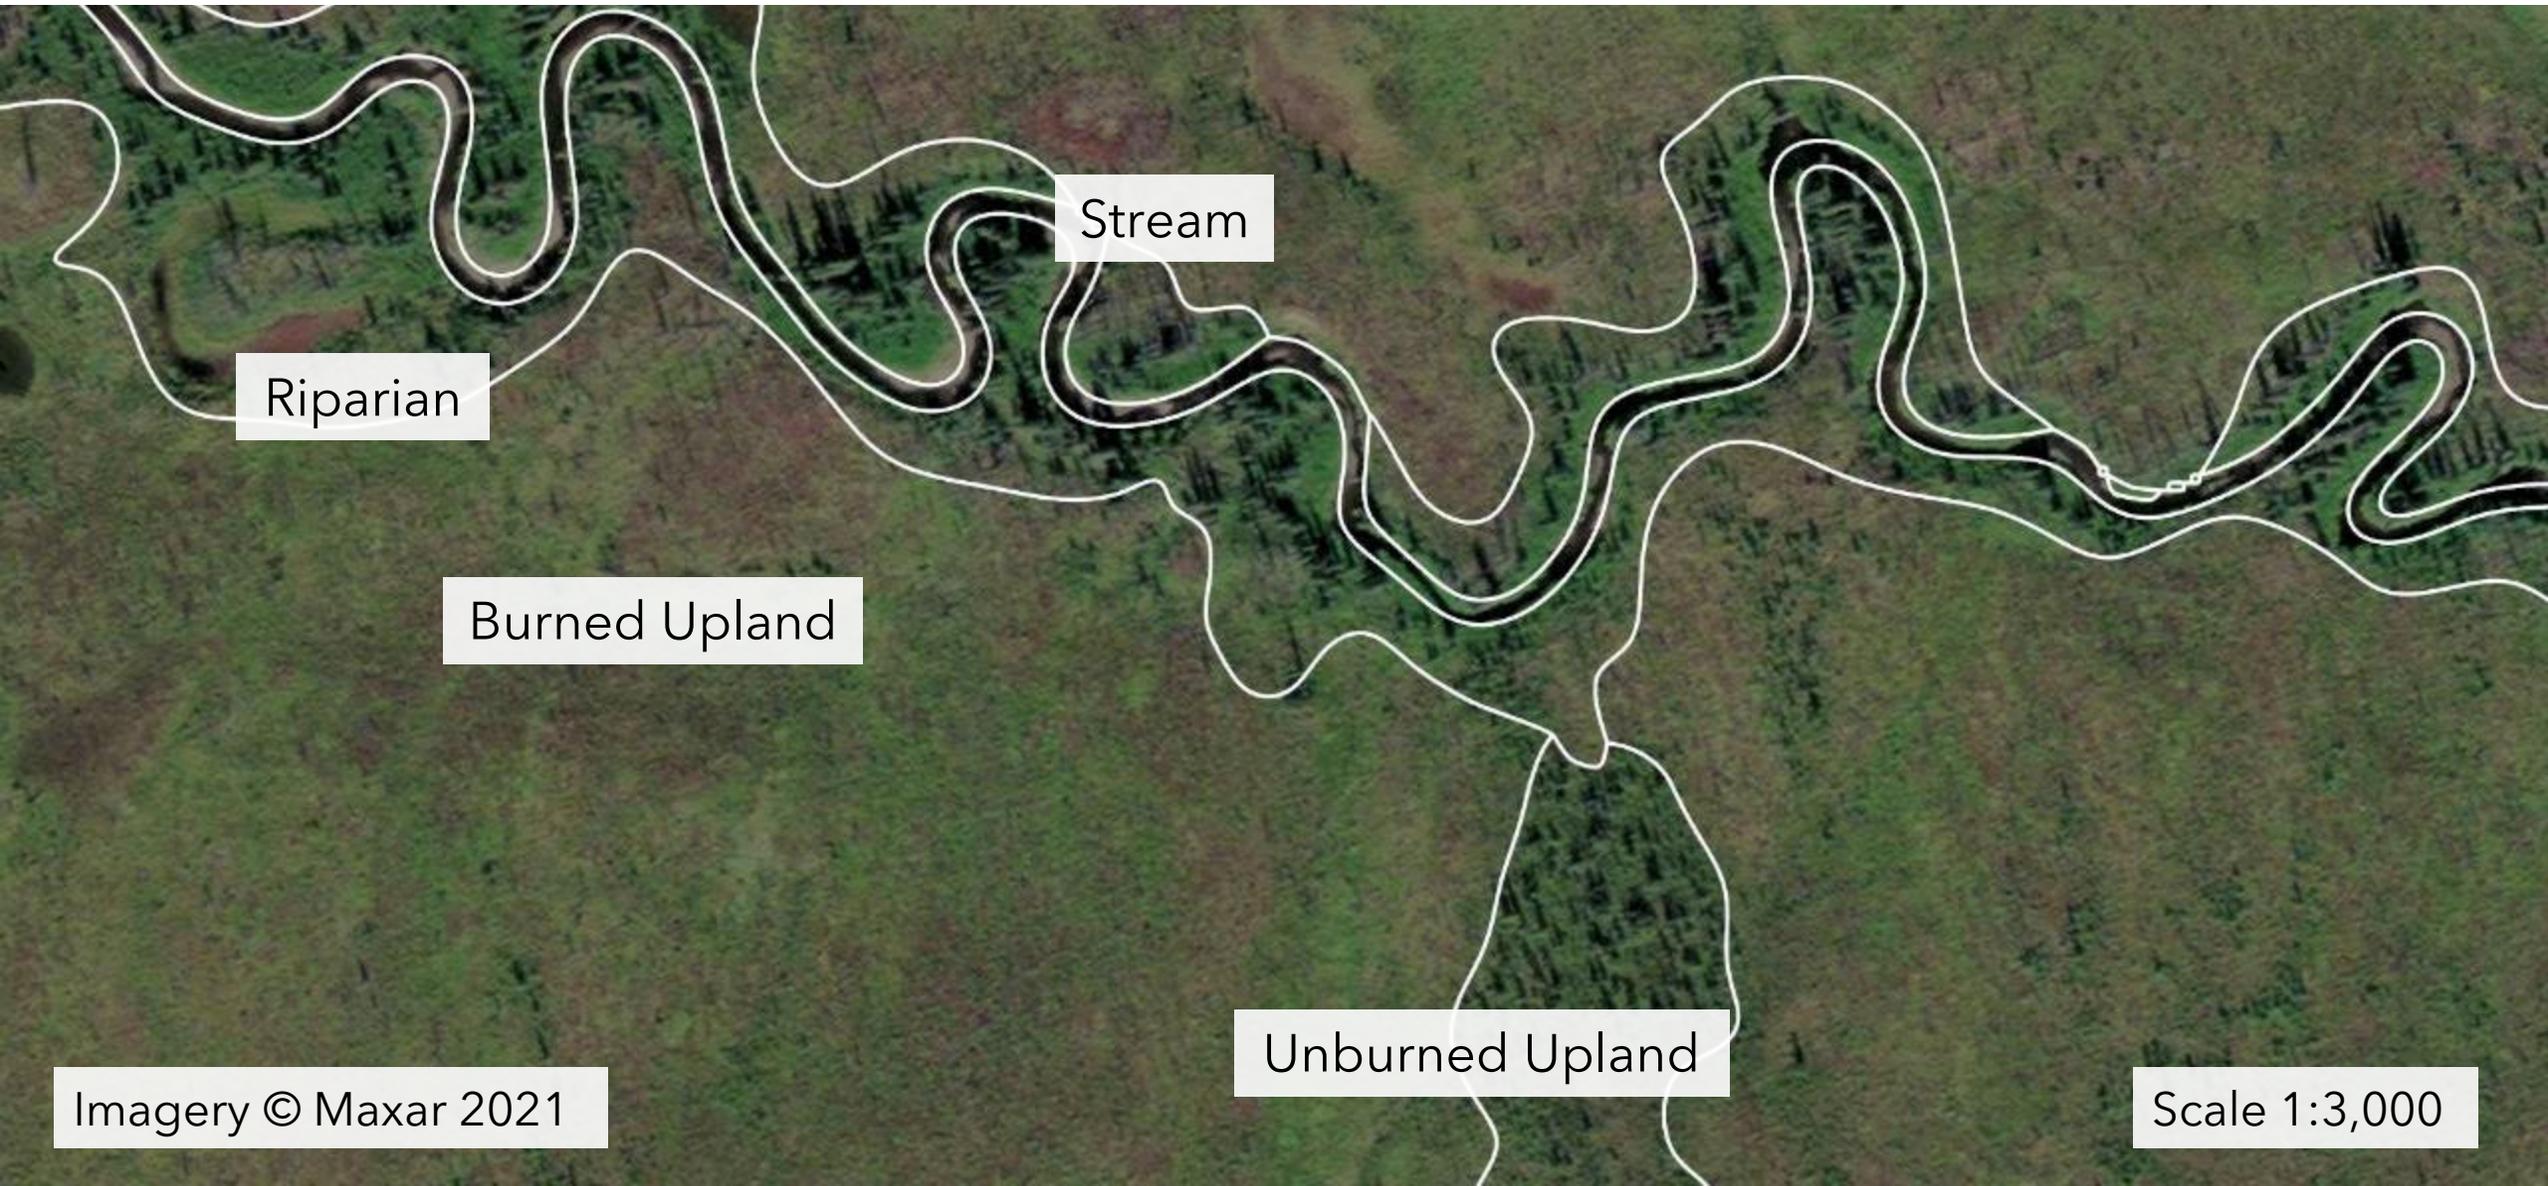

Imagery © Maxar 2021

Scale 1:3,000

Form polygons based on aggregated model predictions

# Aggregate to MMU (0.5 acre)

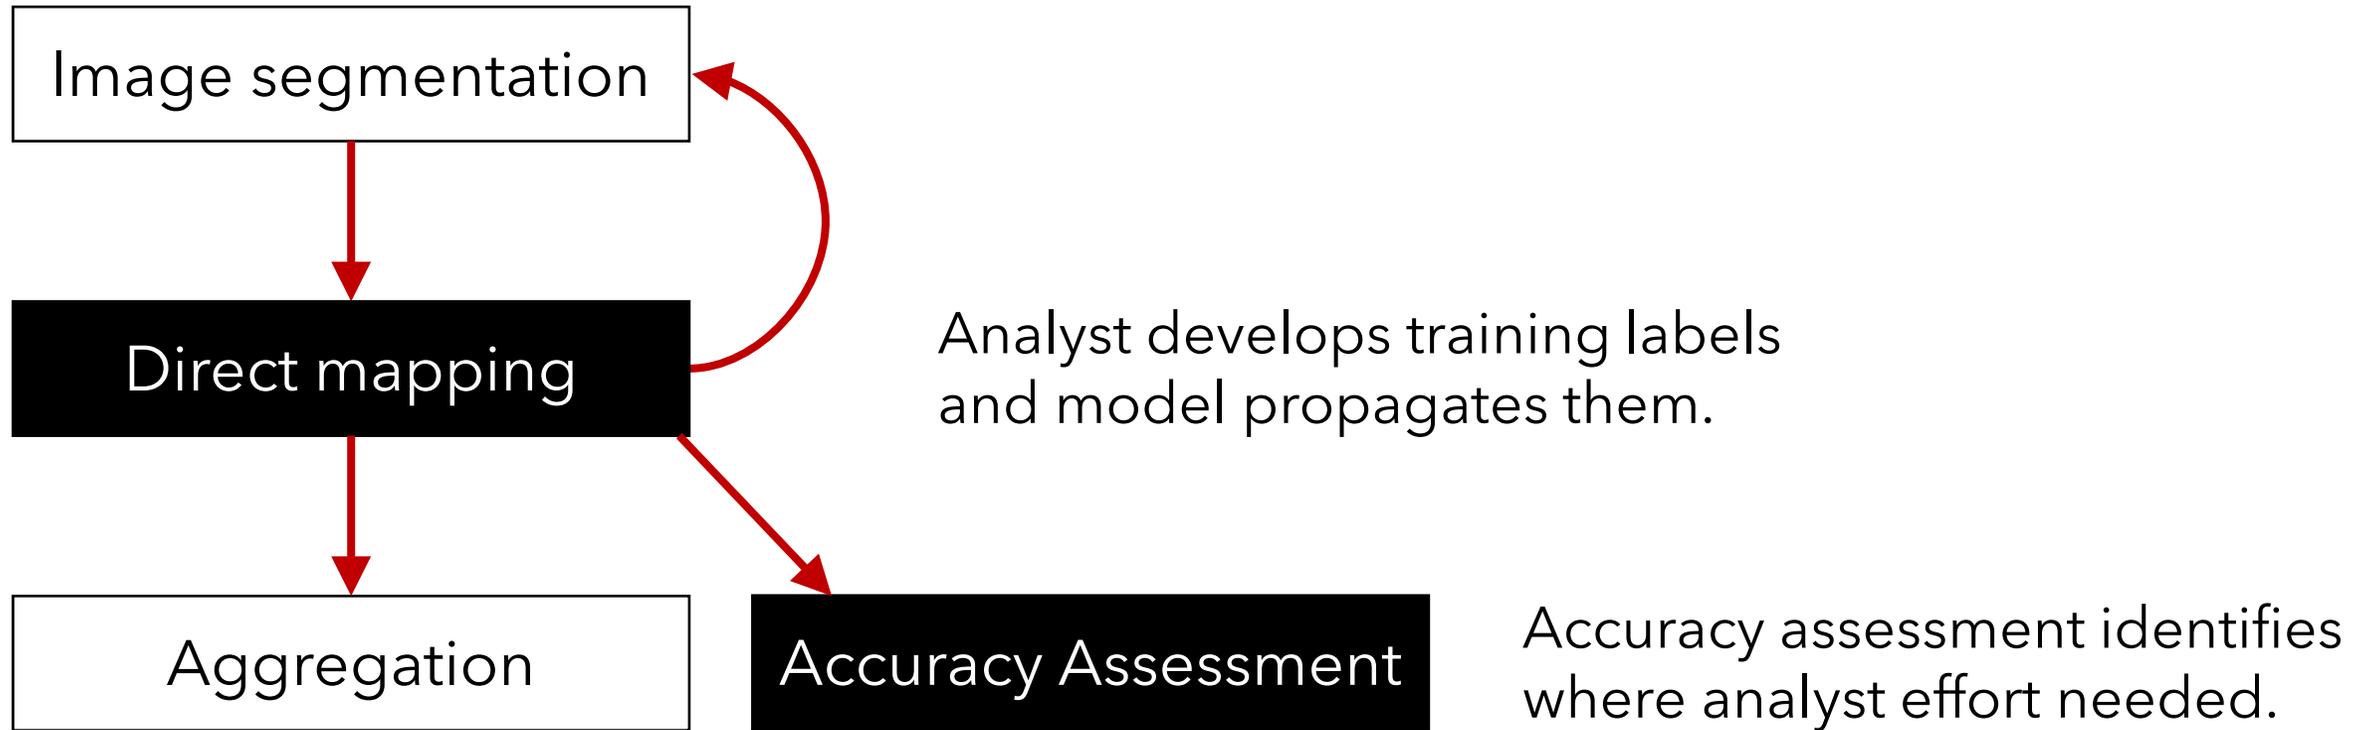

Stream

Riparian

Burned Upland

Unburned Upland

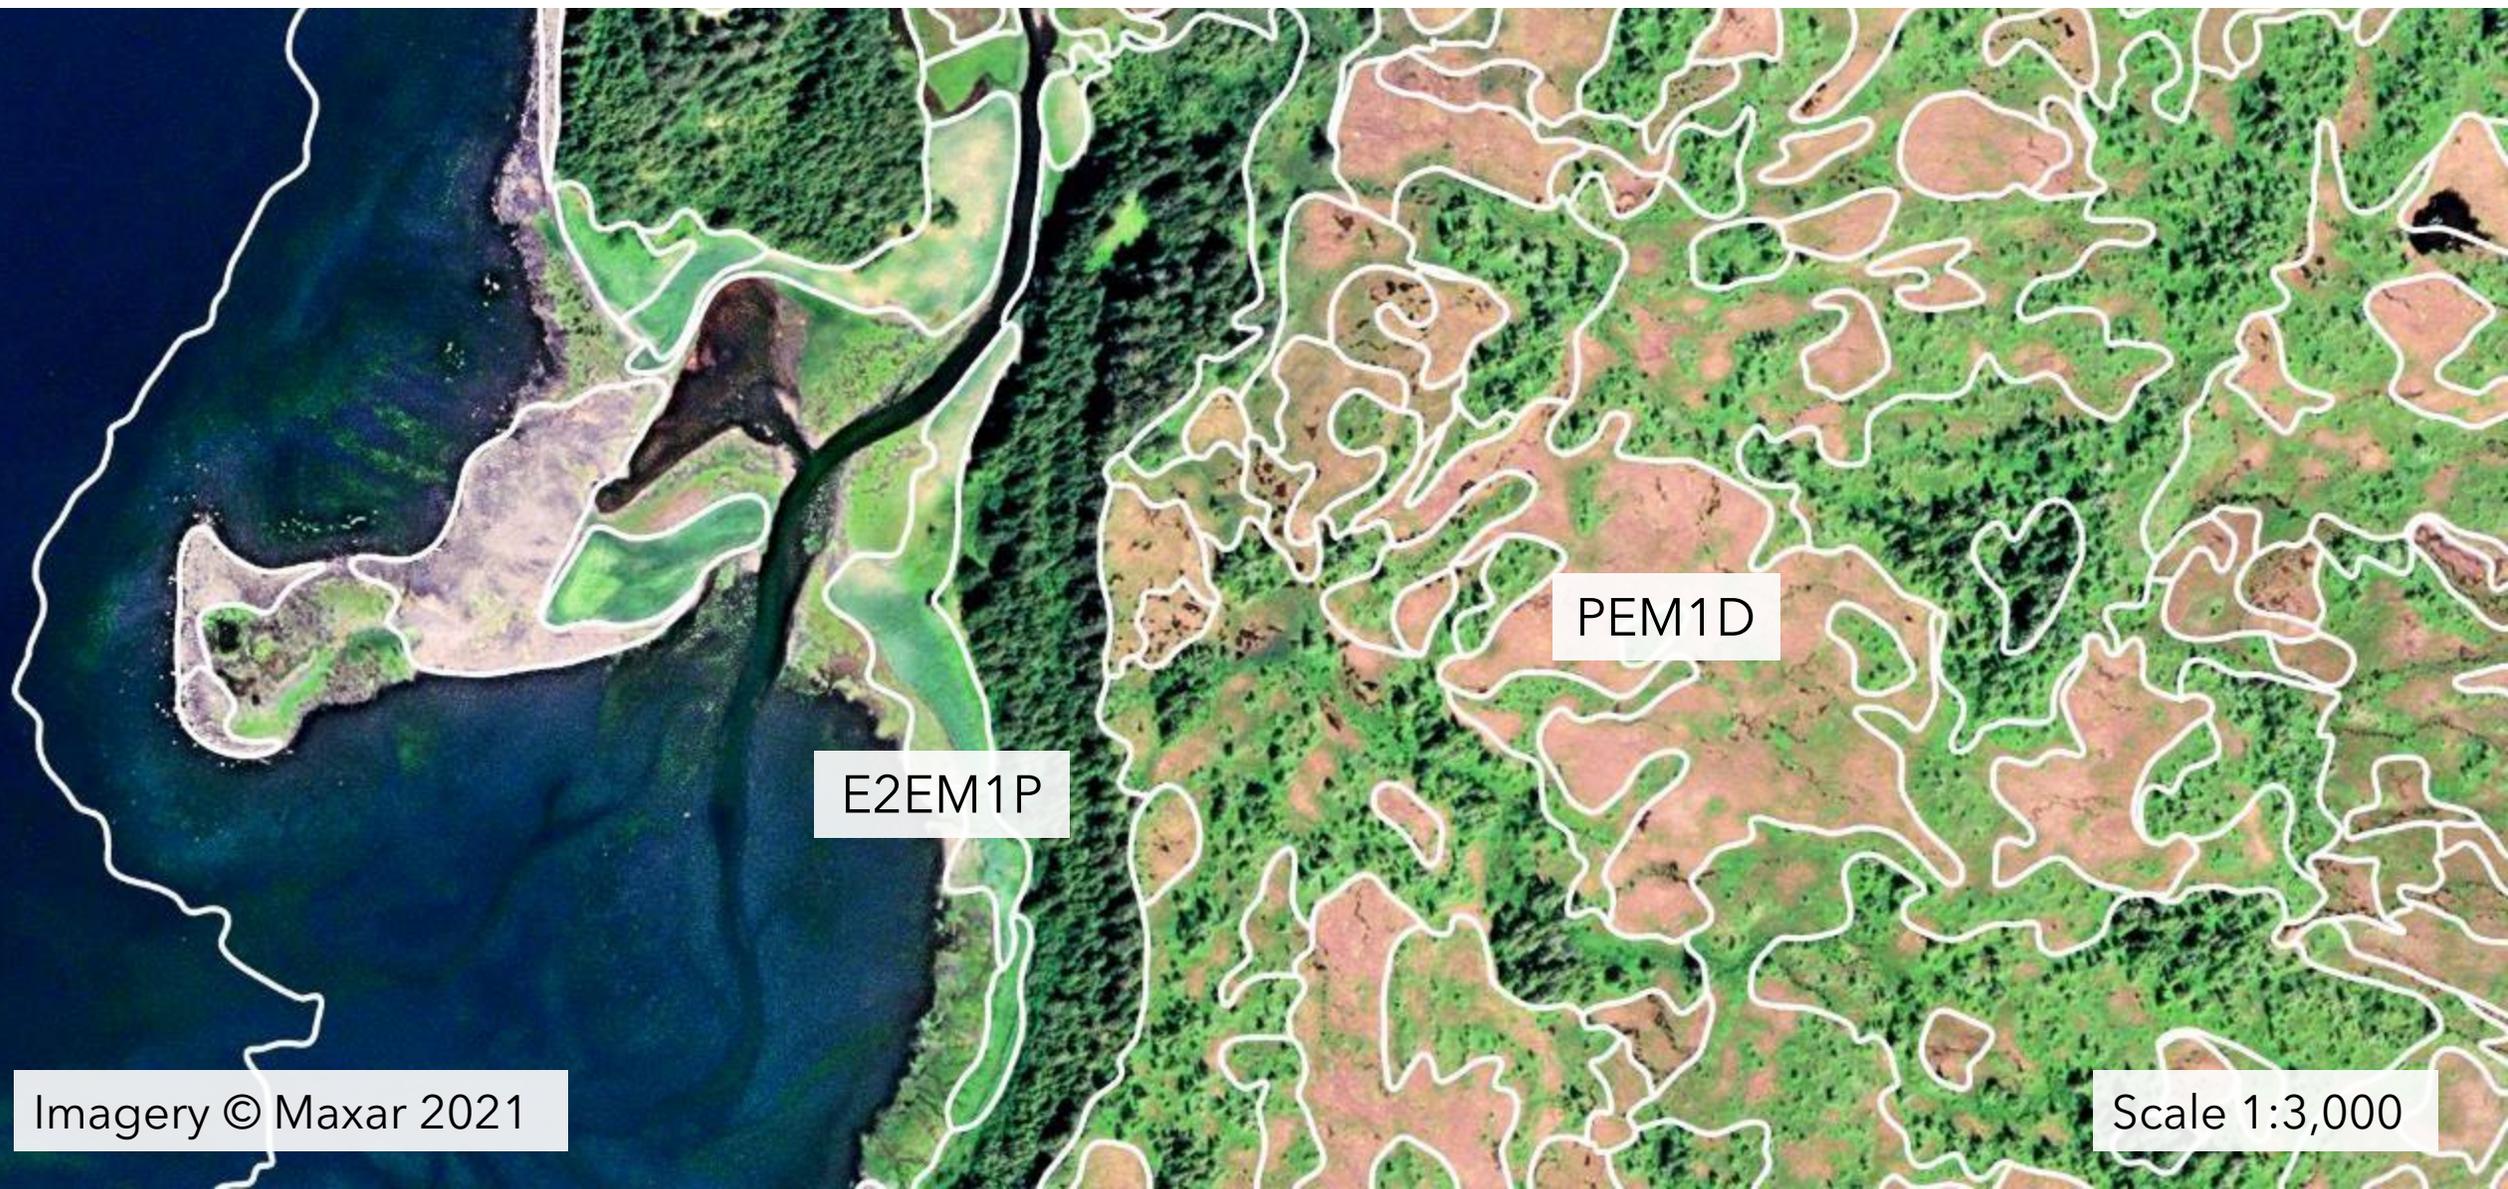

# Semi-automated workflow

Direct mapping starts with manual training polygons

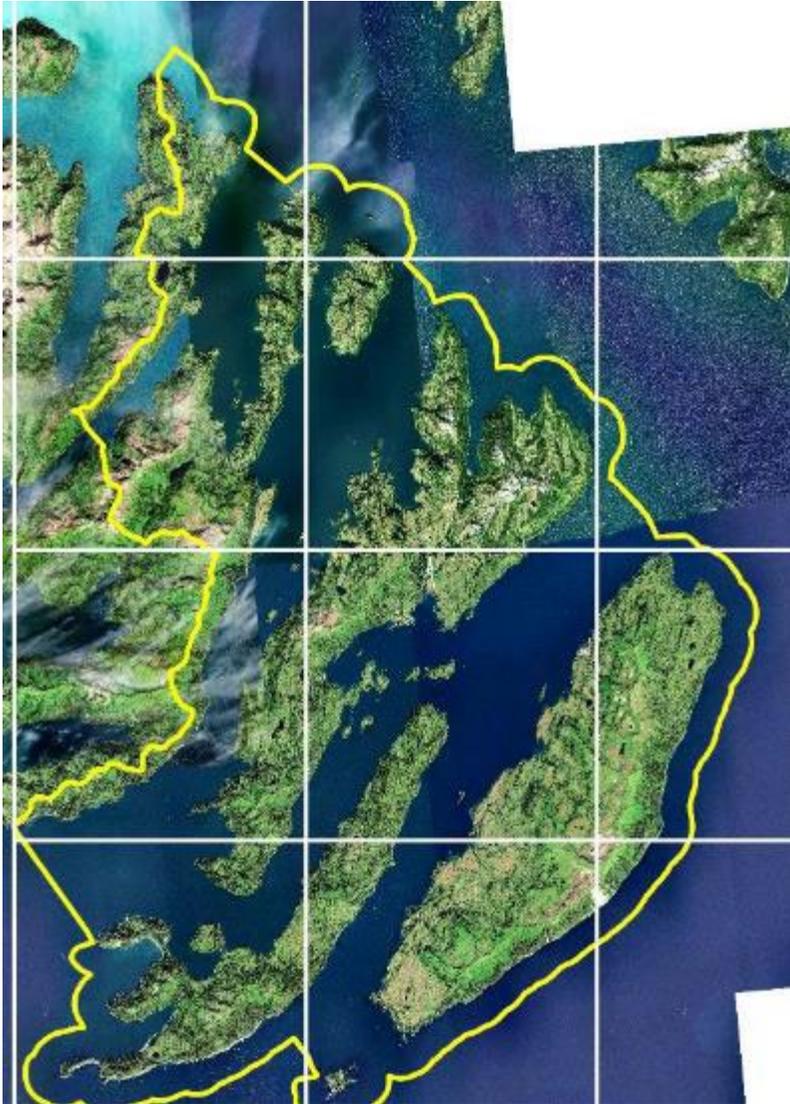

Propagate labels to segments using trained model

Imagery © Maxar 2021

Scale 1:3,000

# Statistically robust accuracy assessment

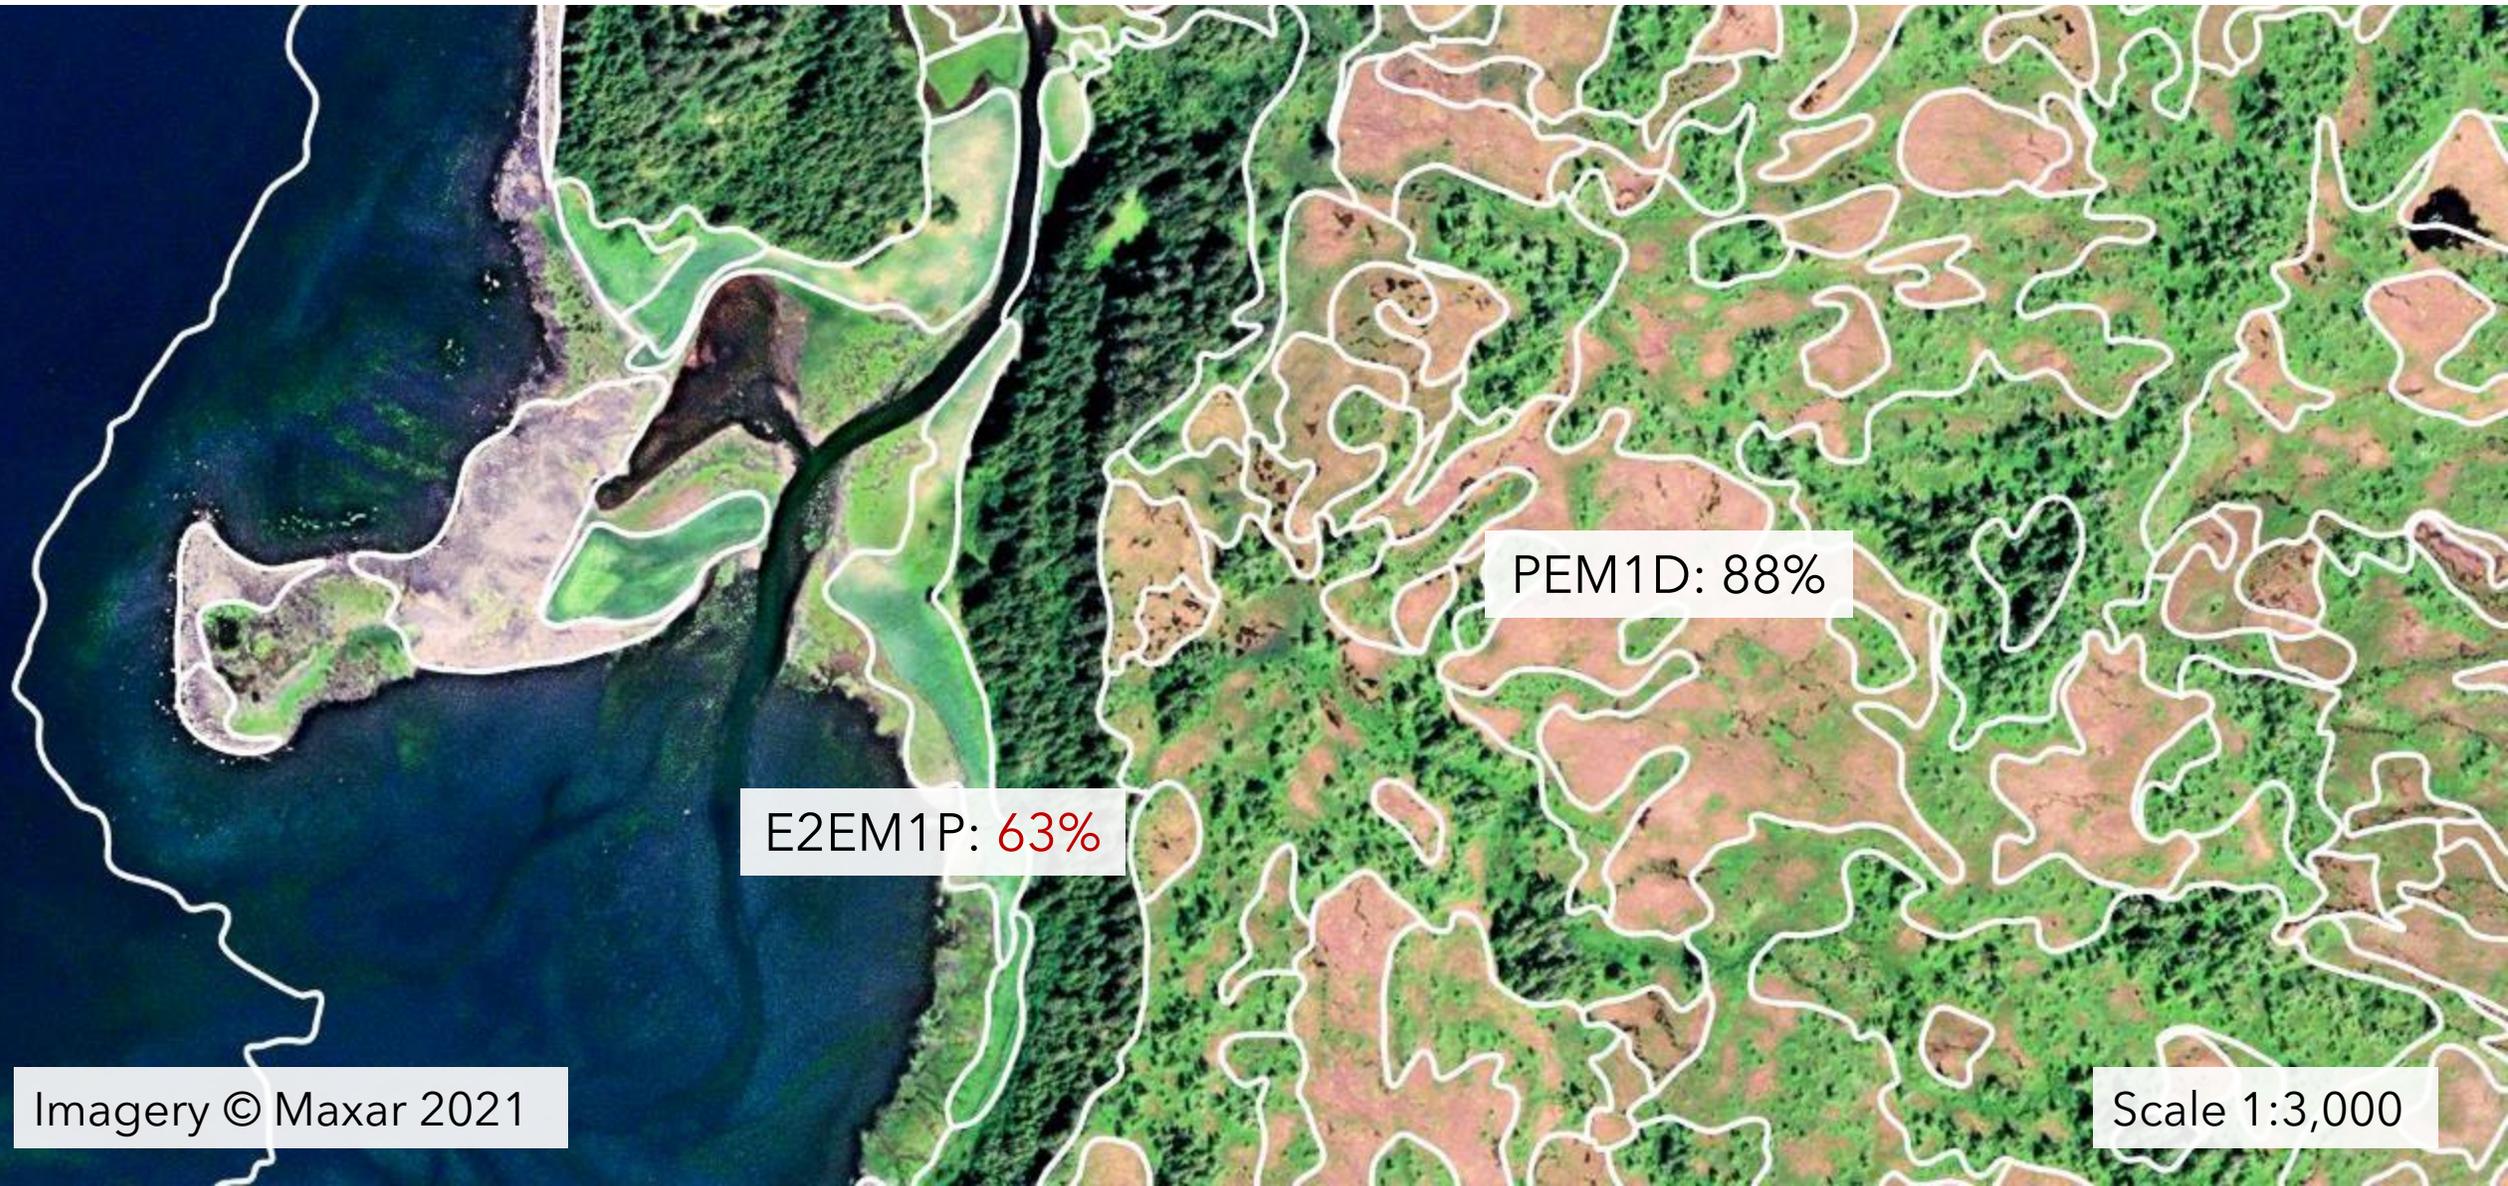

Study area (yellow) divided into cross validation blocks (white)

Training data in each block retained once as independent test partition of cross validation

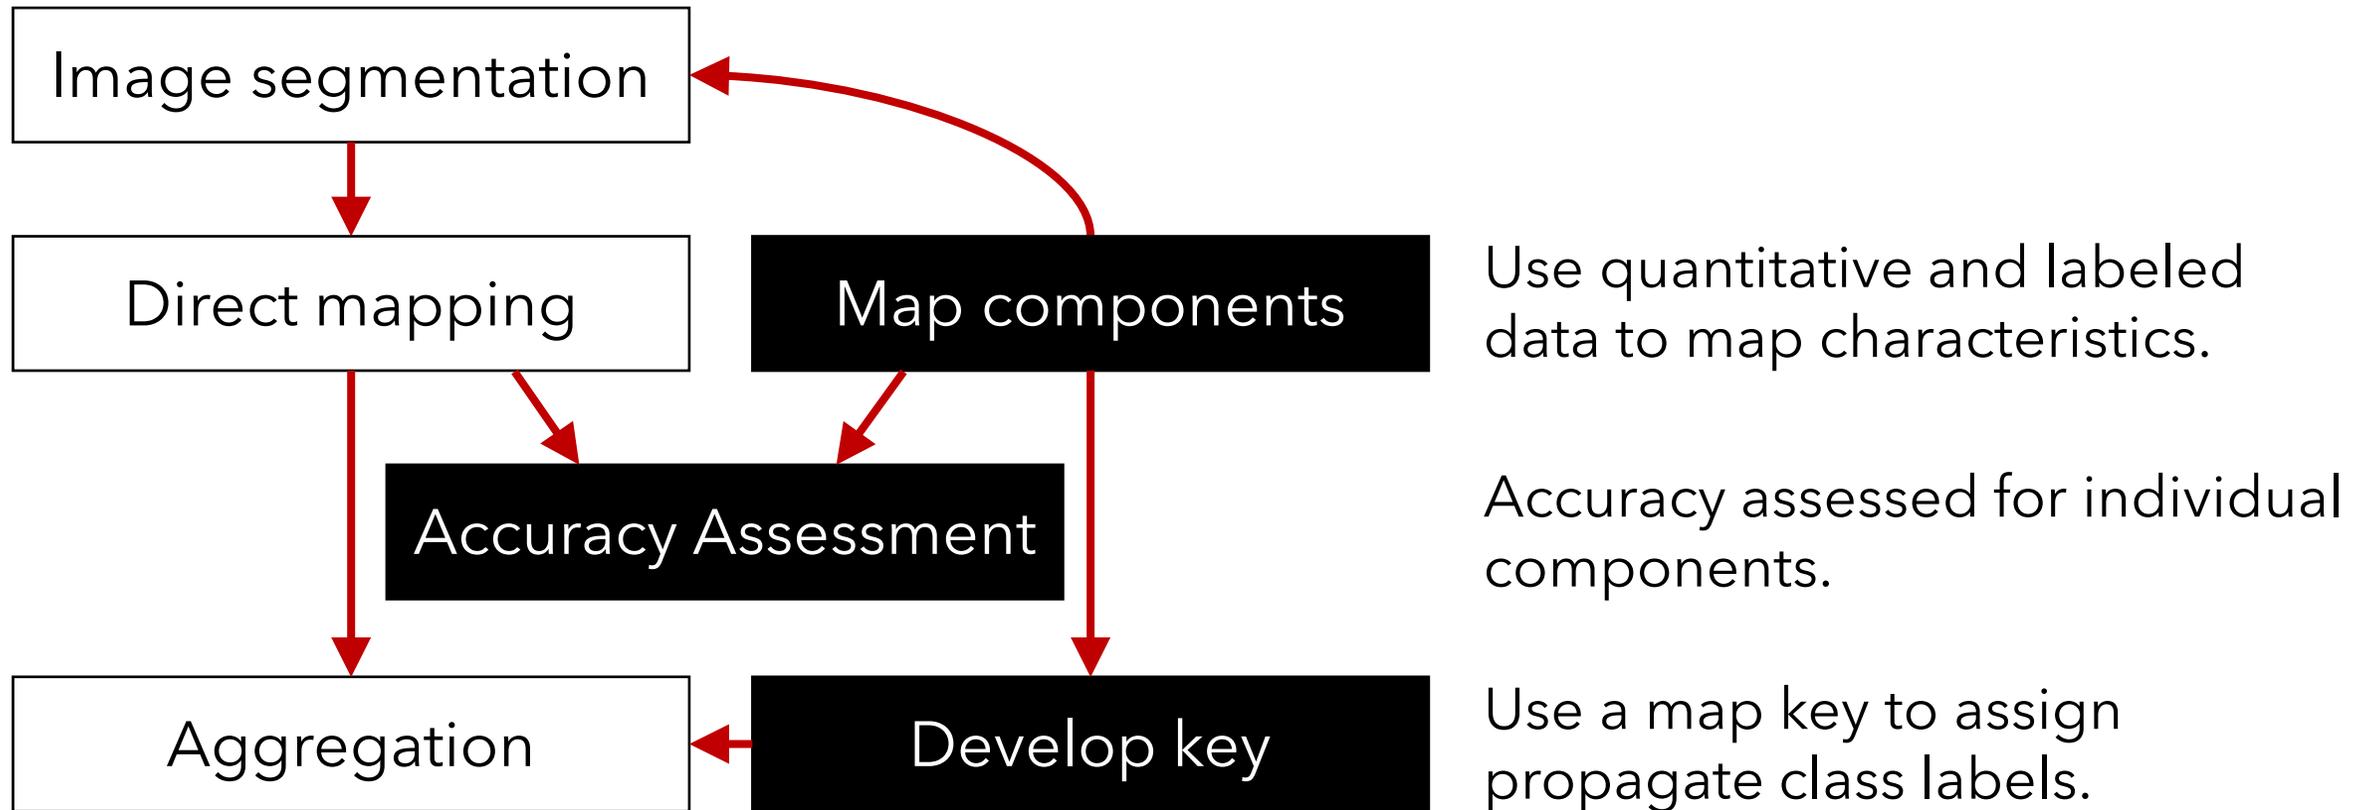

Identifies problems related to:

1. Misclassification/omission
2. Ecological ambiguity
3. Analyst errors/inconsistency
4. Additional data needs
5. Model error (analyst's effort needed)

Identify where analyst's effort is best spent

# Semi-automated workflow

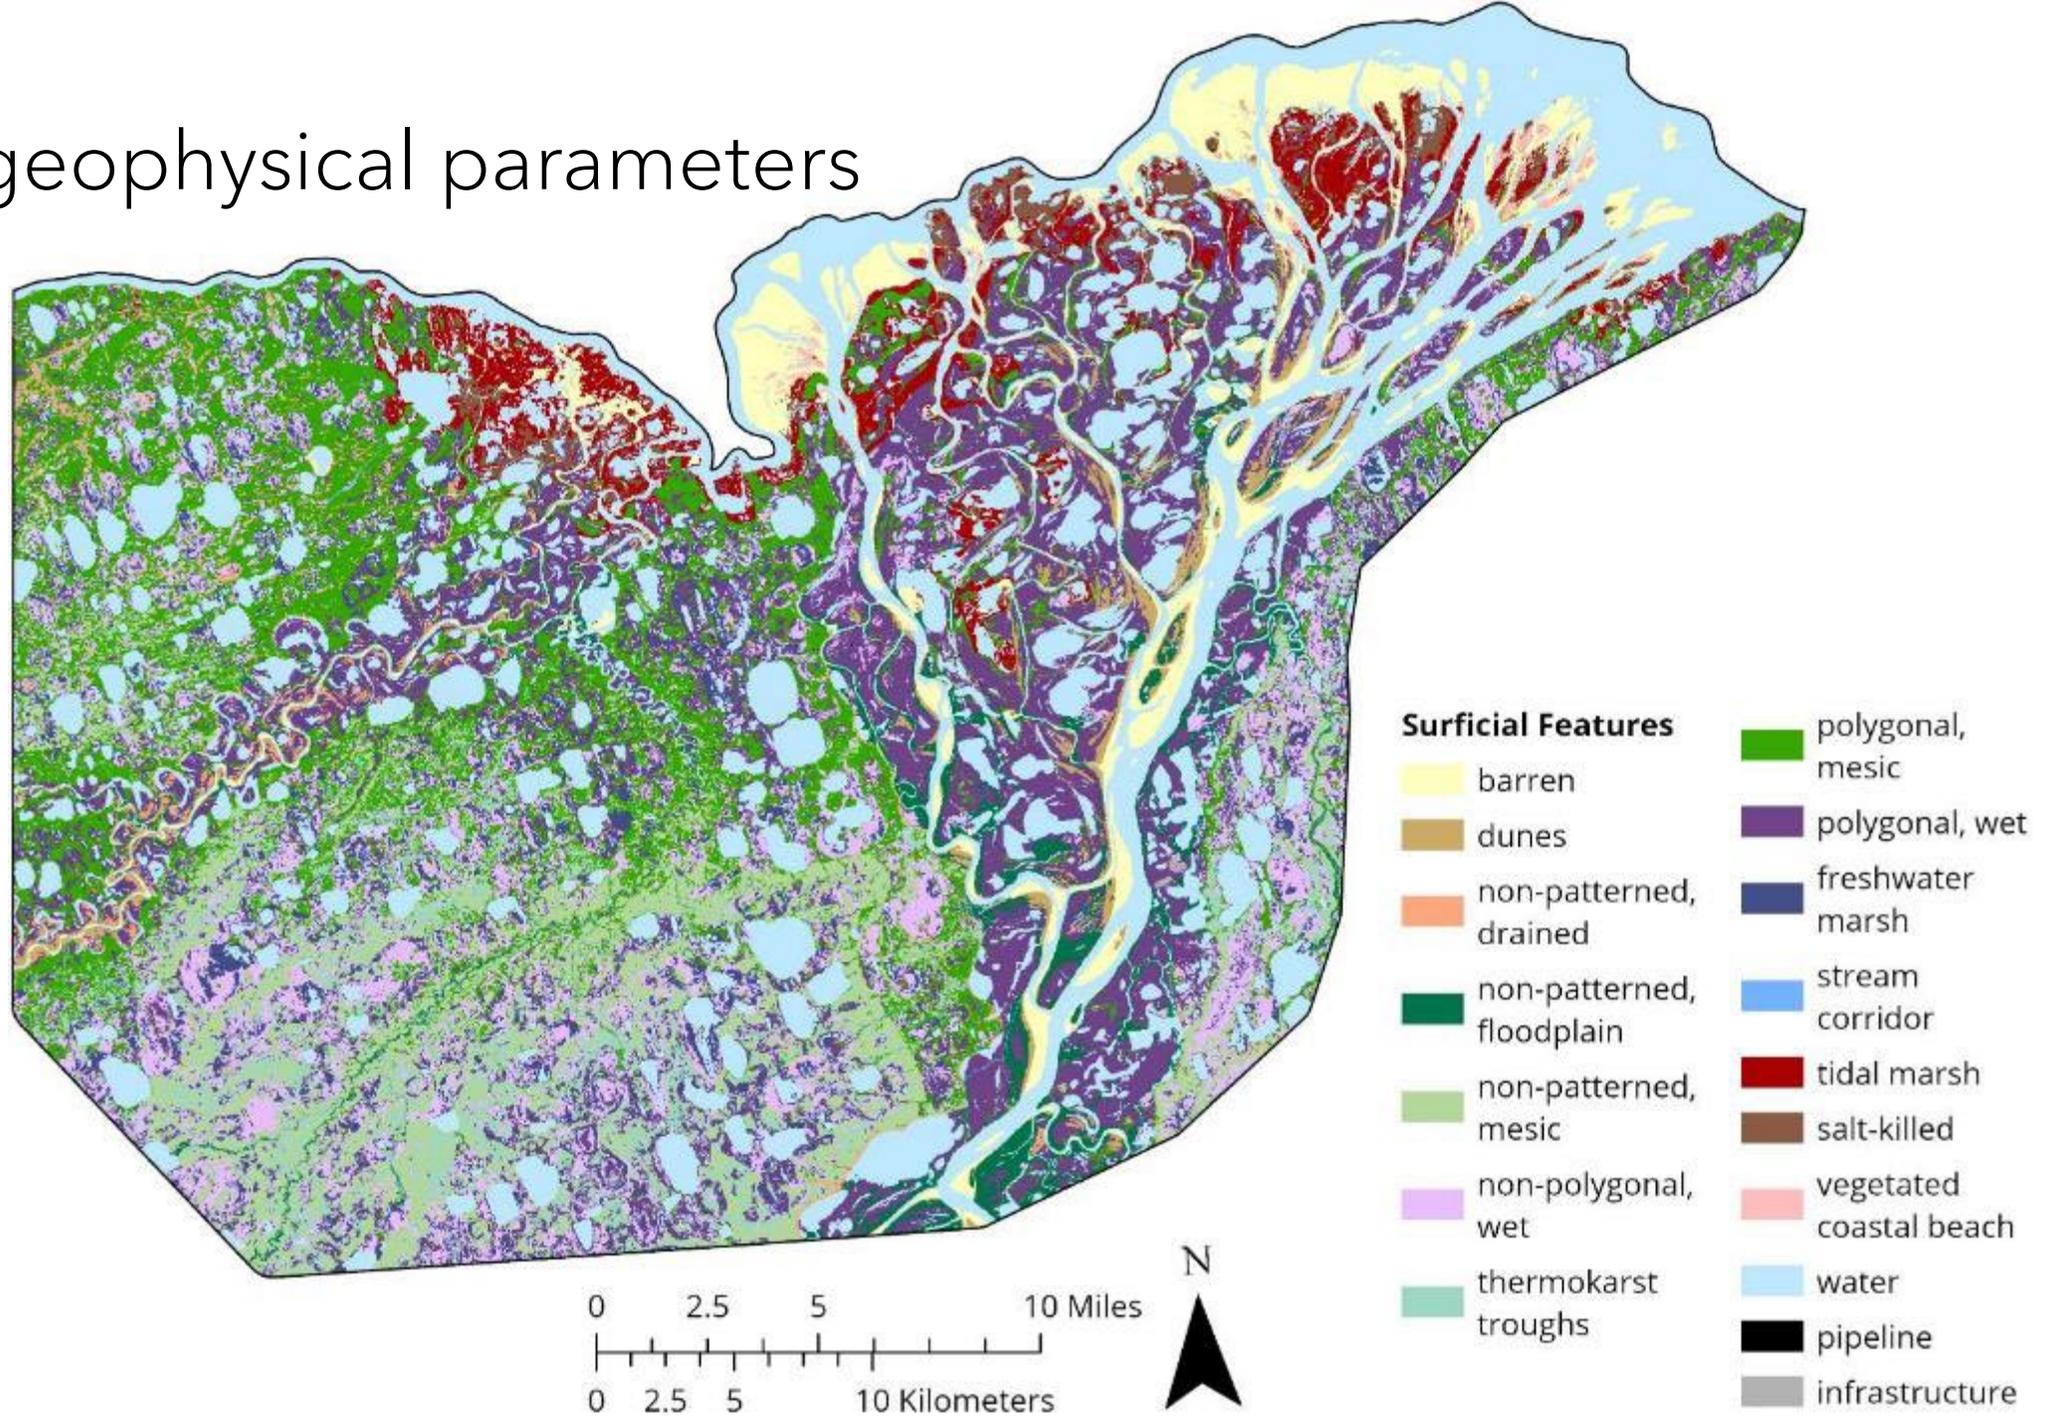

# Mapping wetland components

- *Eriophorum vaginatum* (tussock cottongrass) is FACW
- FACW definition: **predominately occur in hydric soils, geomorphic settings where water saturates or floods the soil at least seasonally.**
- Summary of 187 sites across Alaska of paired vegetation plots and soil pits:
  - 52% of occurrences in mesic soils
  - 48% of occurrences in hydric soils

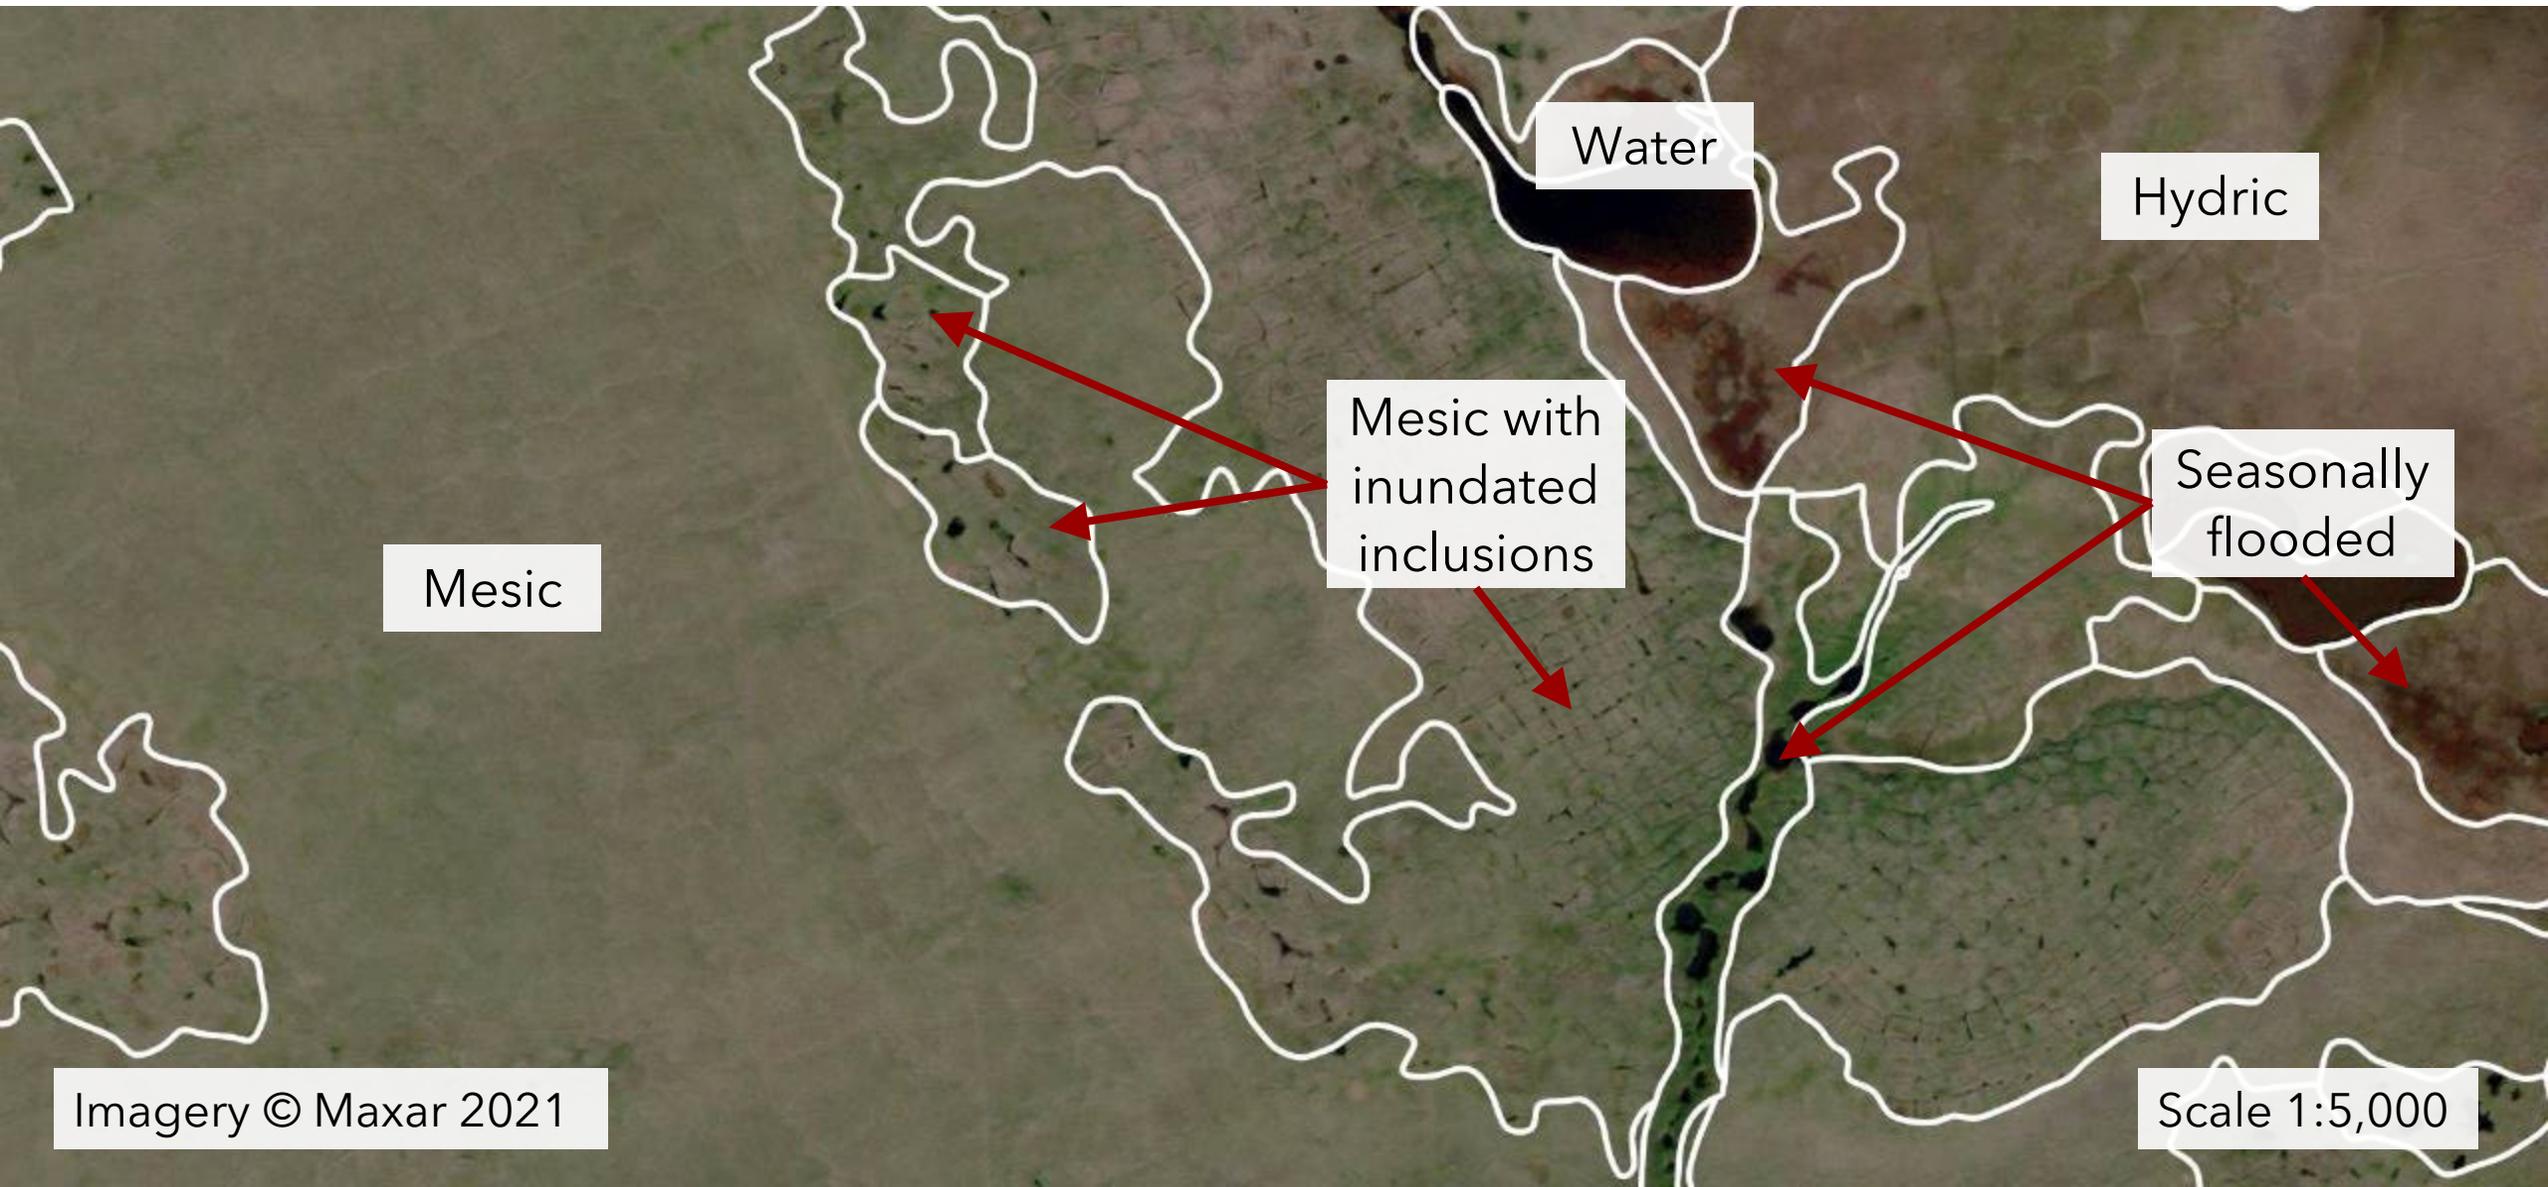

**Net effect: FACW designation drives thousands of acres of 1-parameter mapped wetlands**

# Soil and geophysical parameters

# Map root zone moisture regime and geophysical features

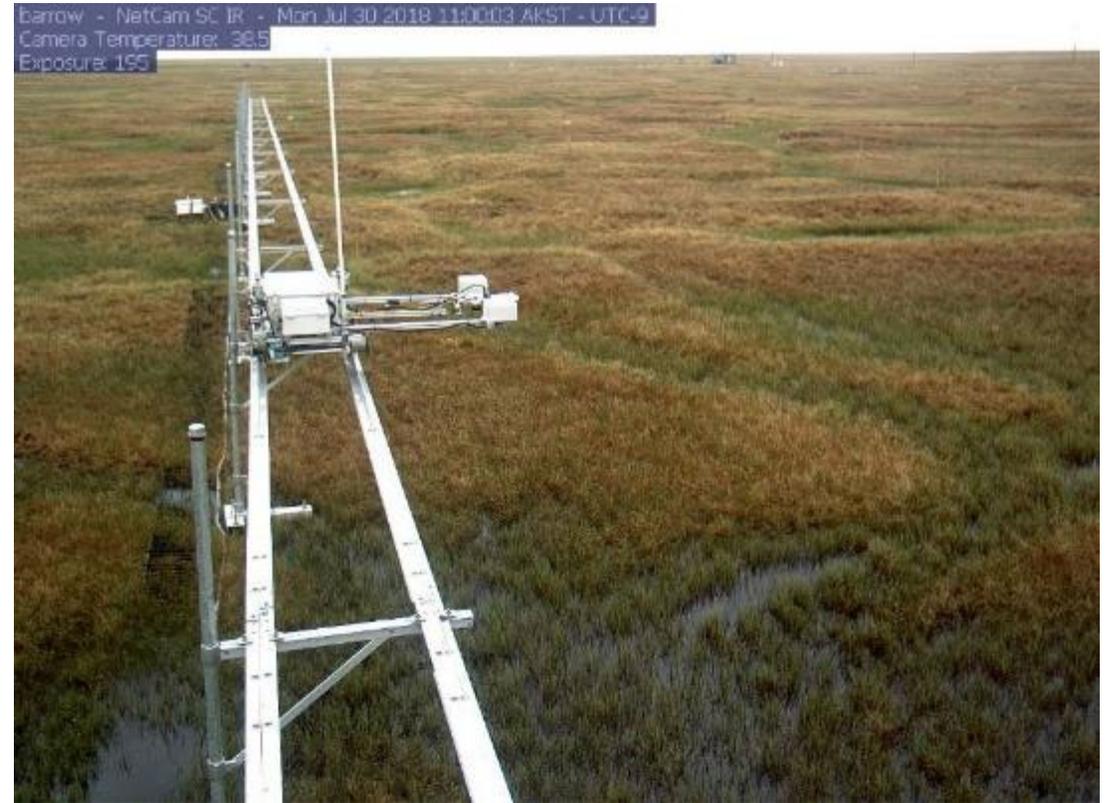

# Growing season % surface water

Percent of season when surface water is present

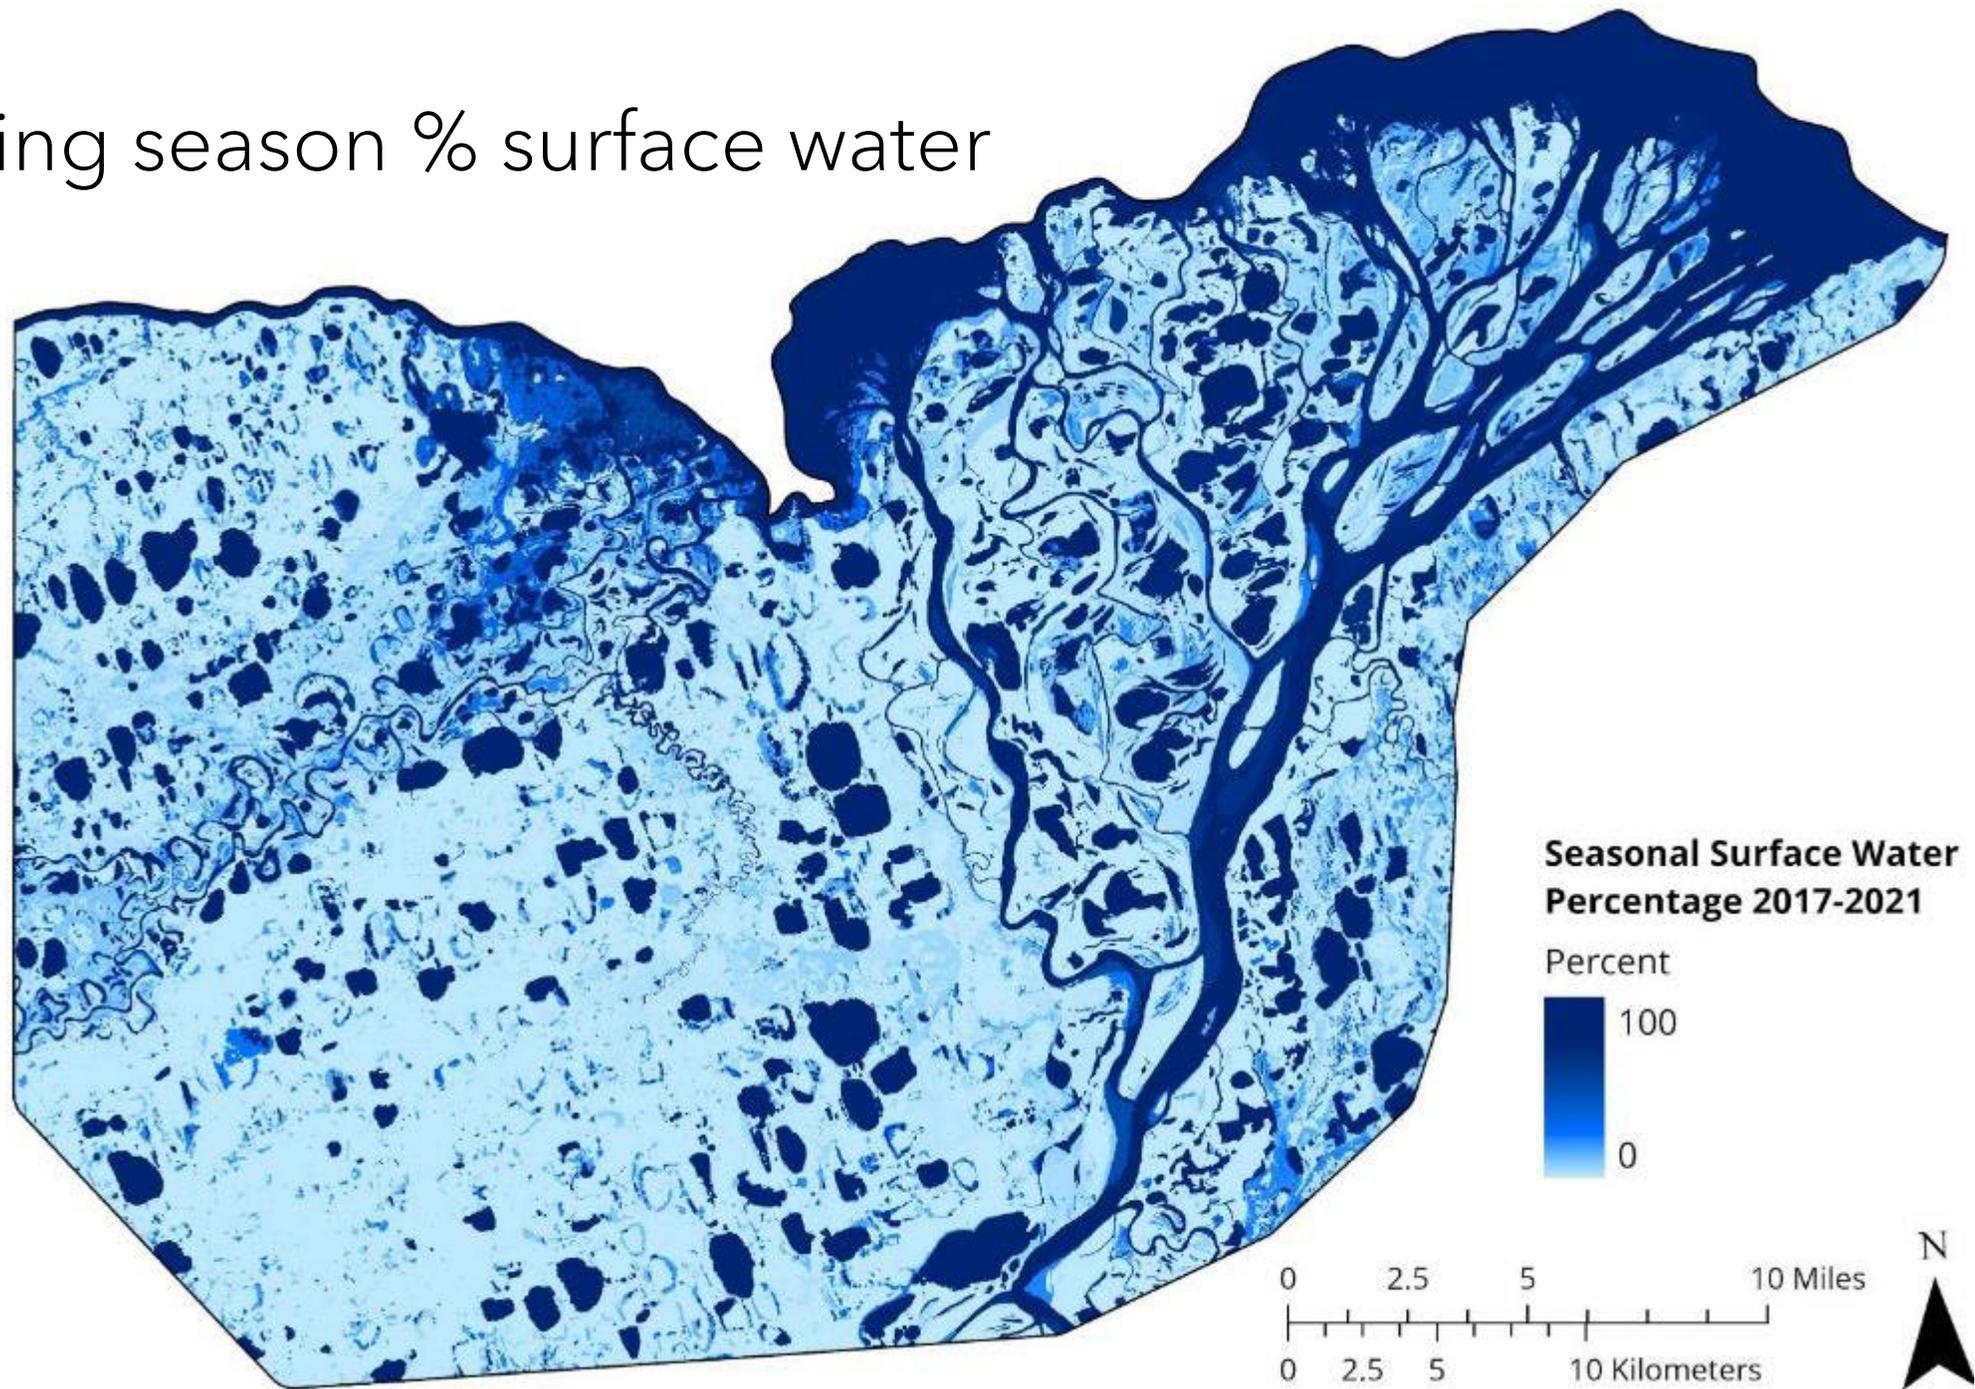

Surface water on June 27, 2018

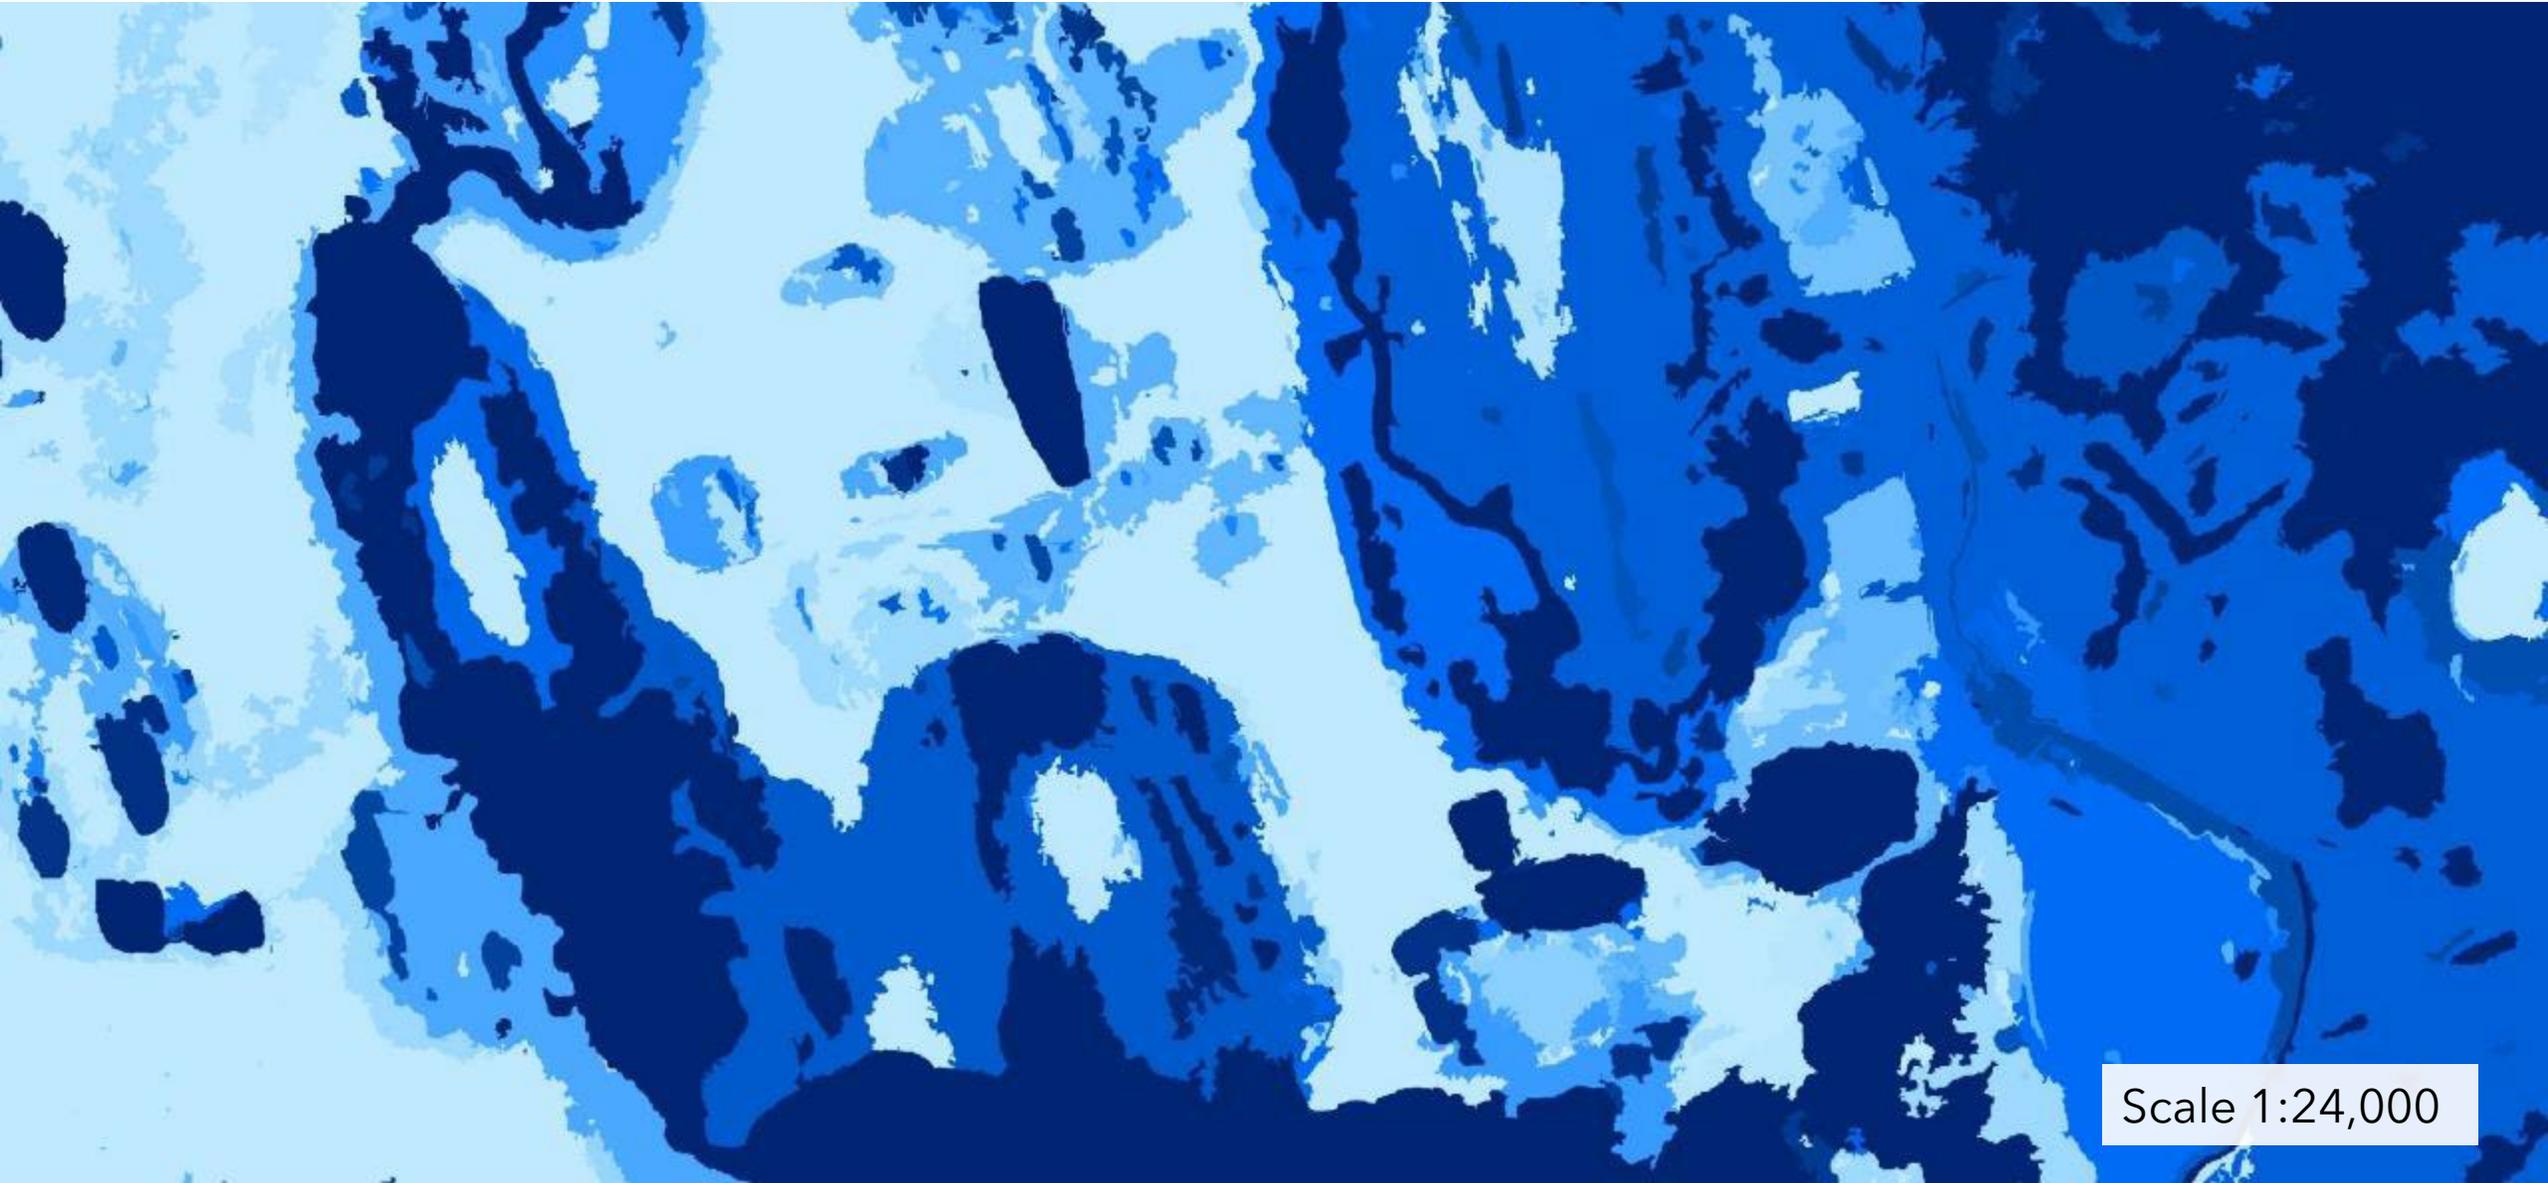

Not surface water (overtopped) by July 30, 2018

# Growing season % surface water

Tidal and flooding patterns represented as %

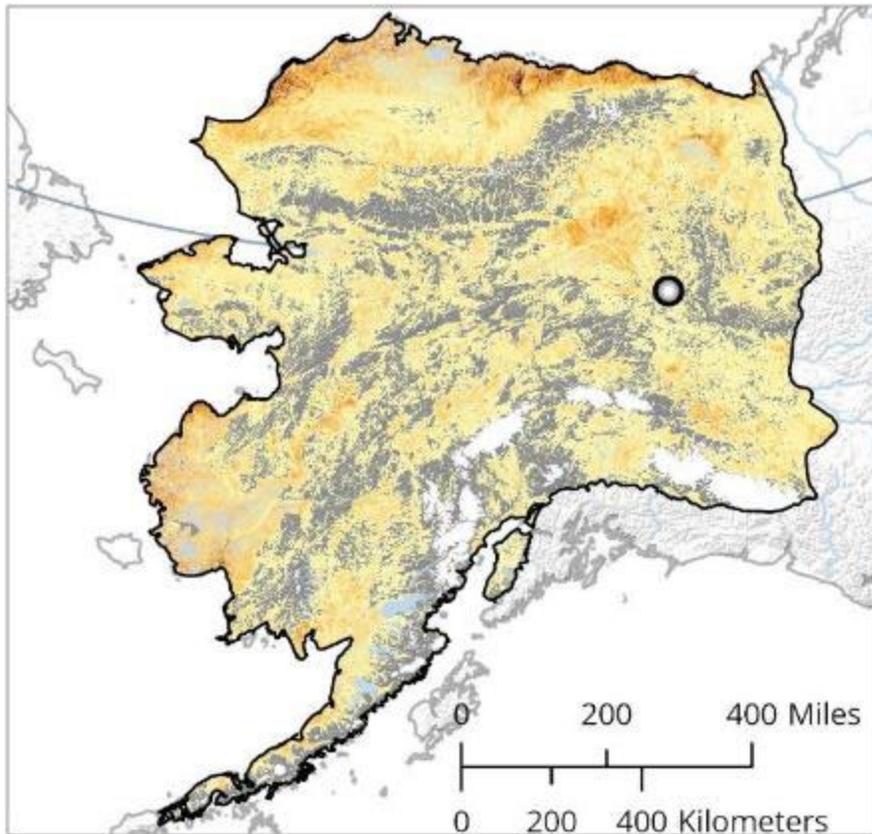

Tidal and flooding patterns represented as %

Imagery © Maxar 2021

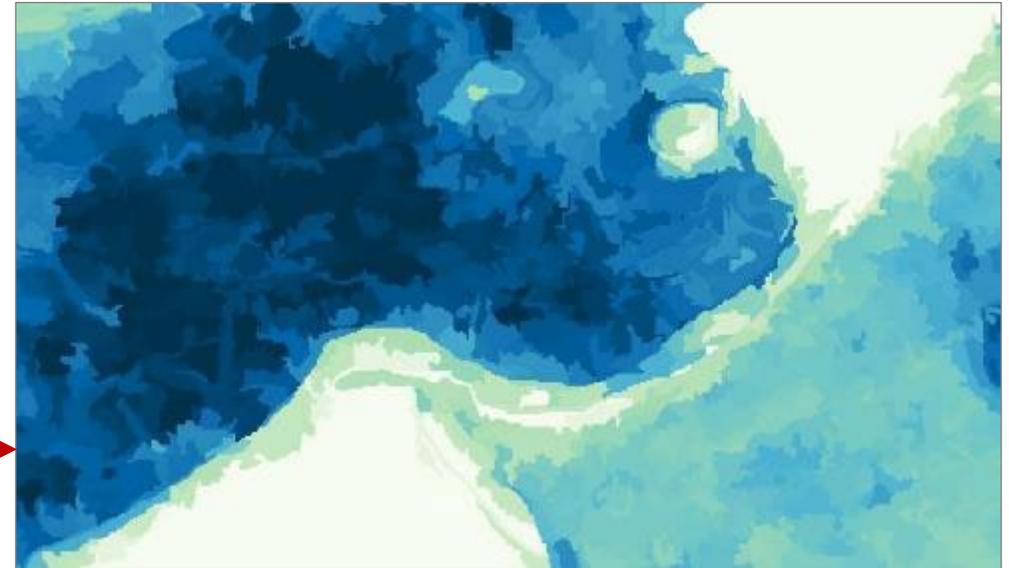

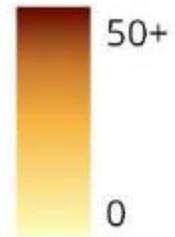

Scale 1:24,000

# Mapping wetland vegetation cover: obligate wetland sedges

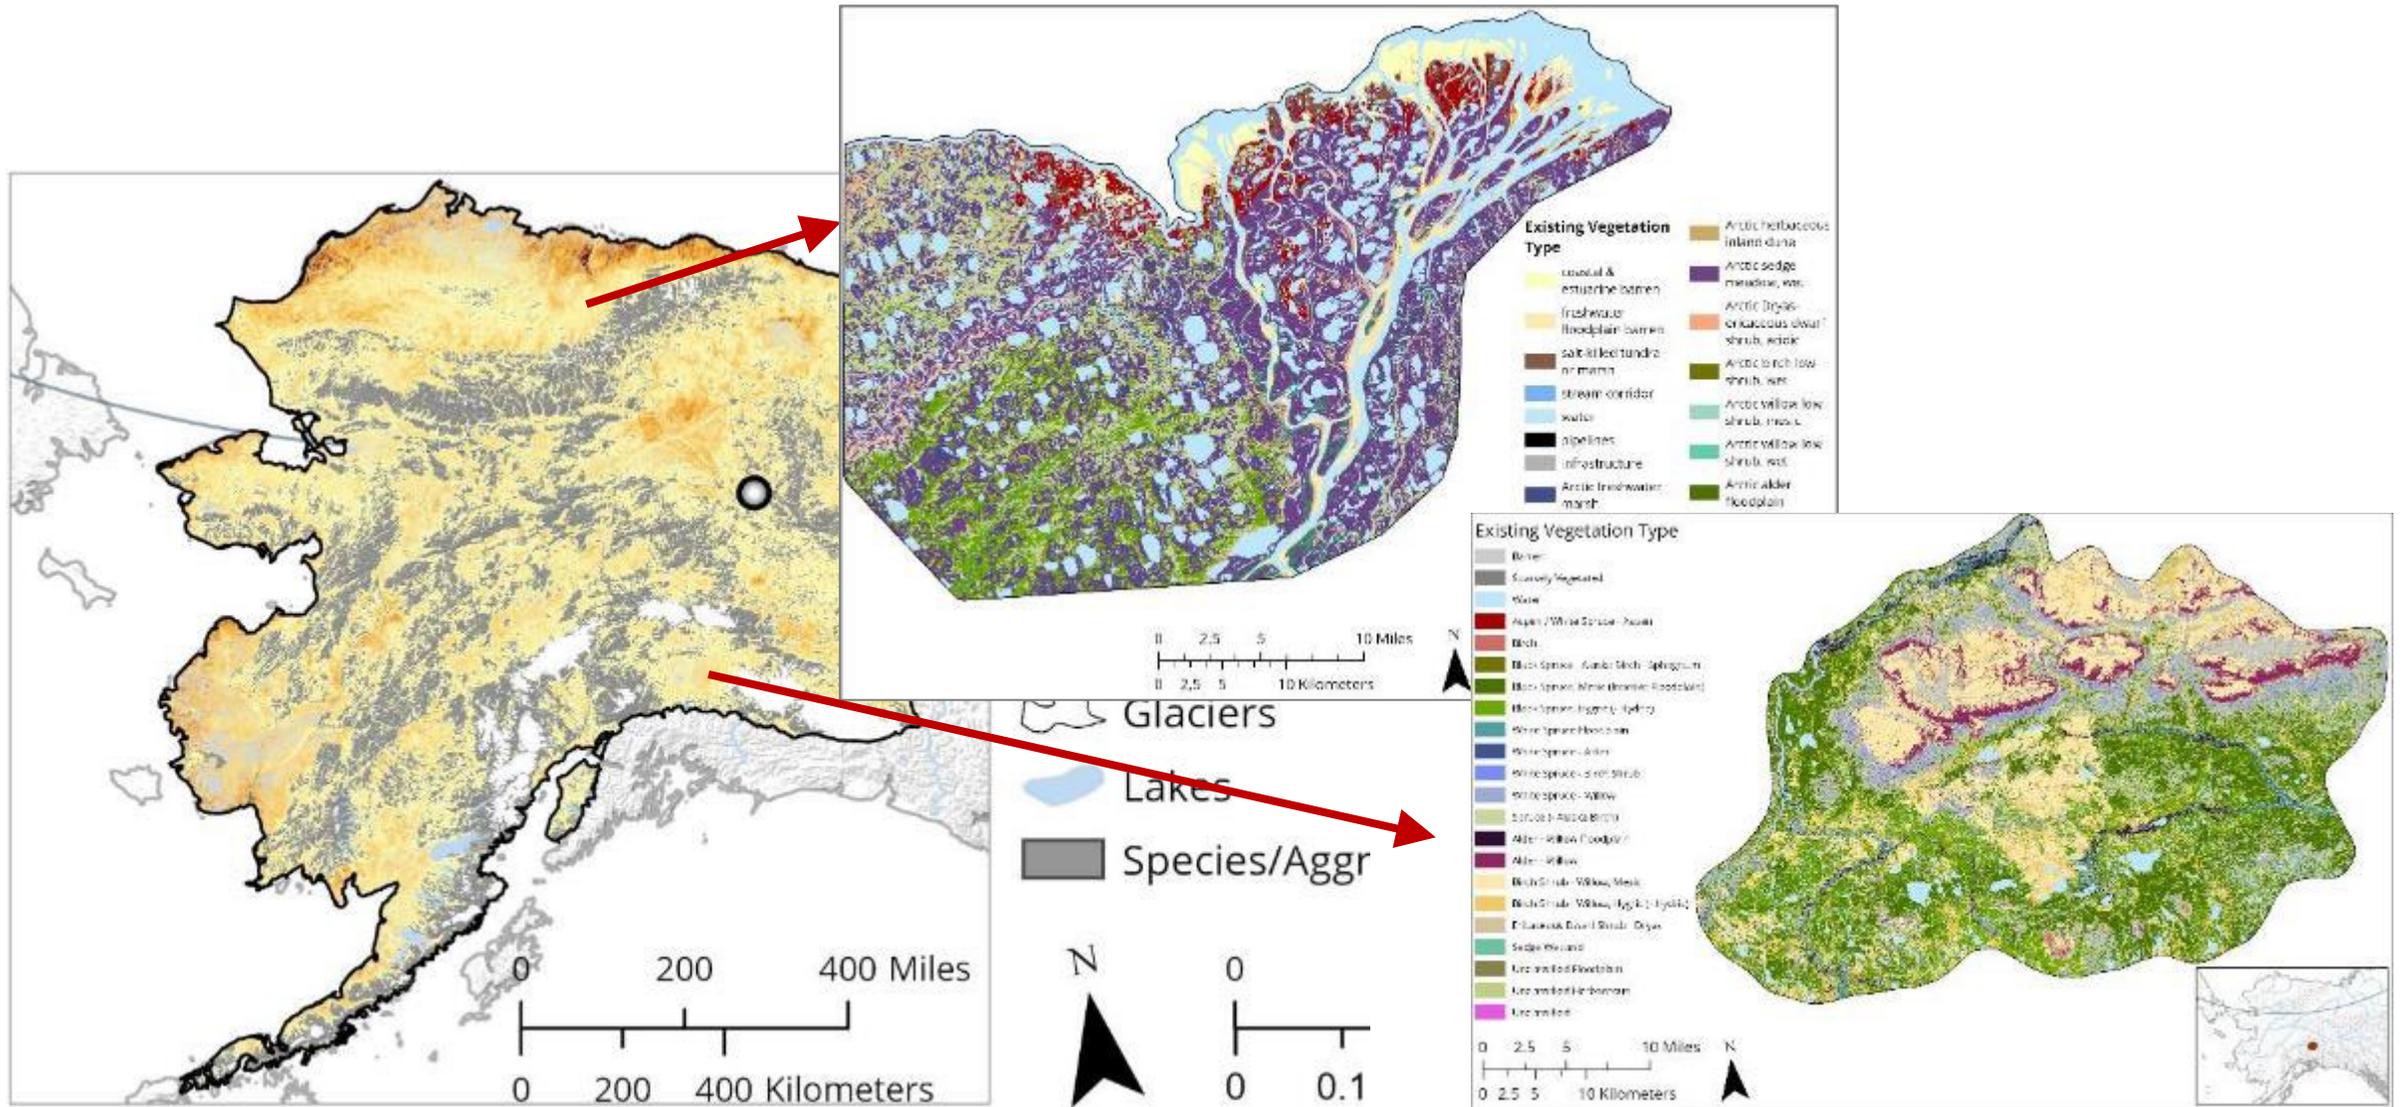

## Wetland Sedges

Foliar Cover (%)

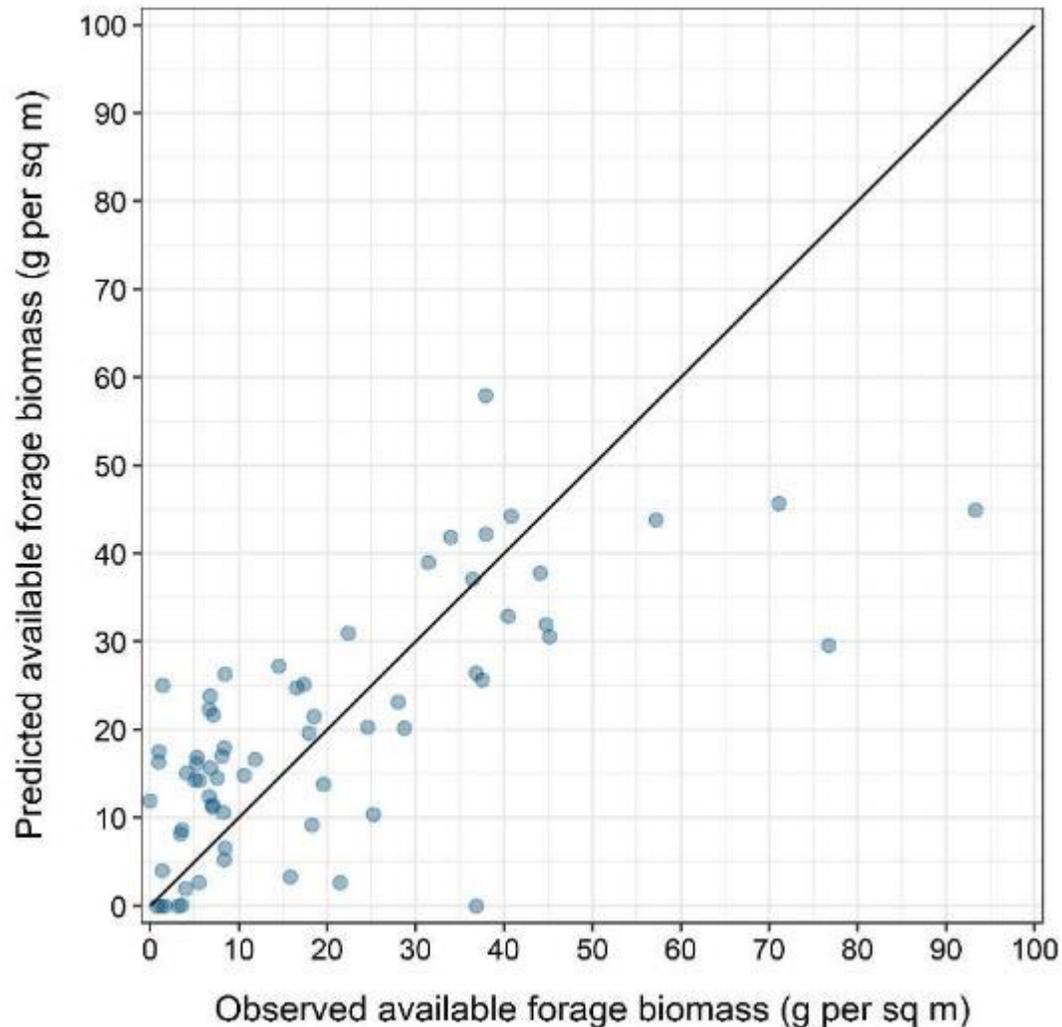

Imagery © Maxar 2021

# Consistent and cost efficient for large regions

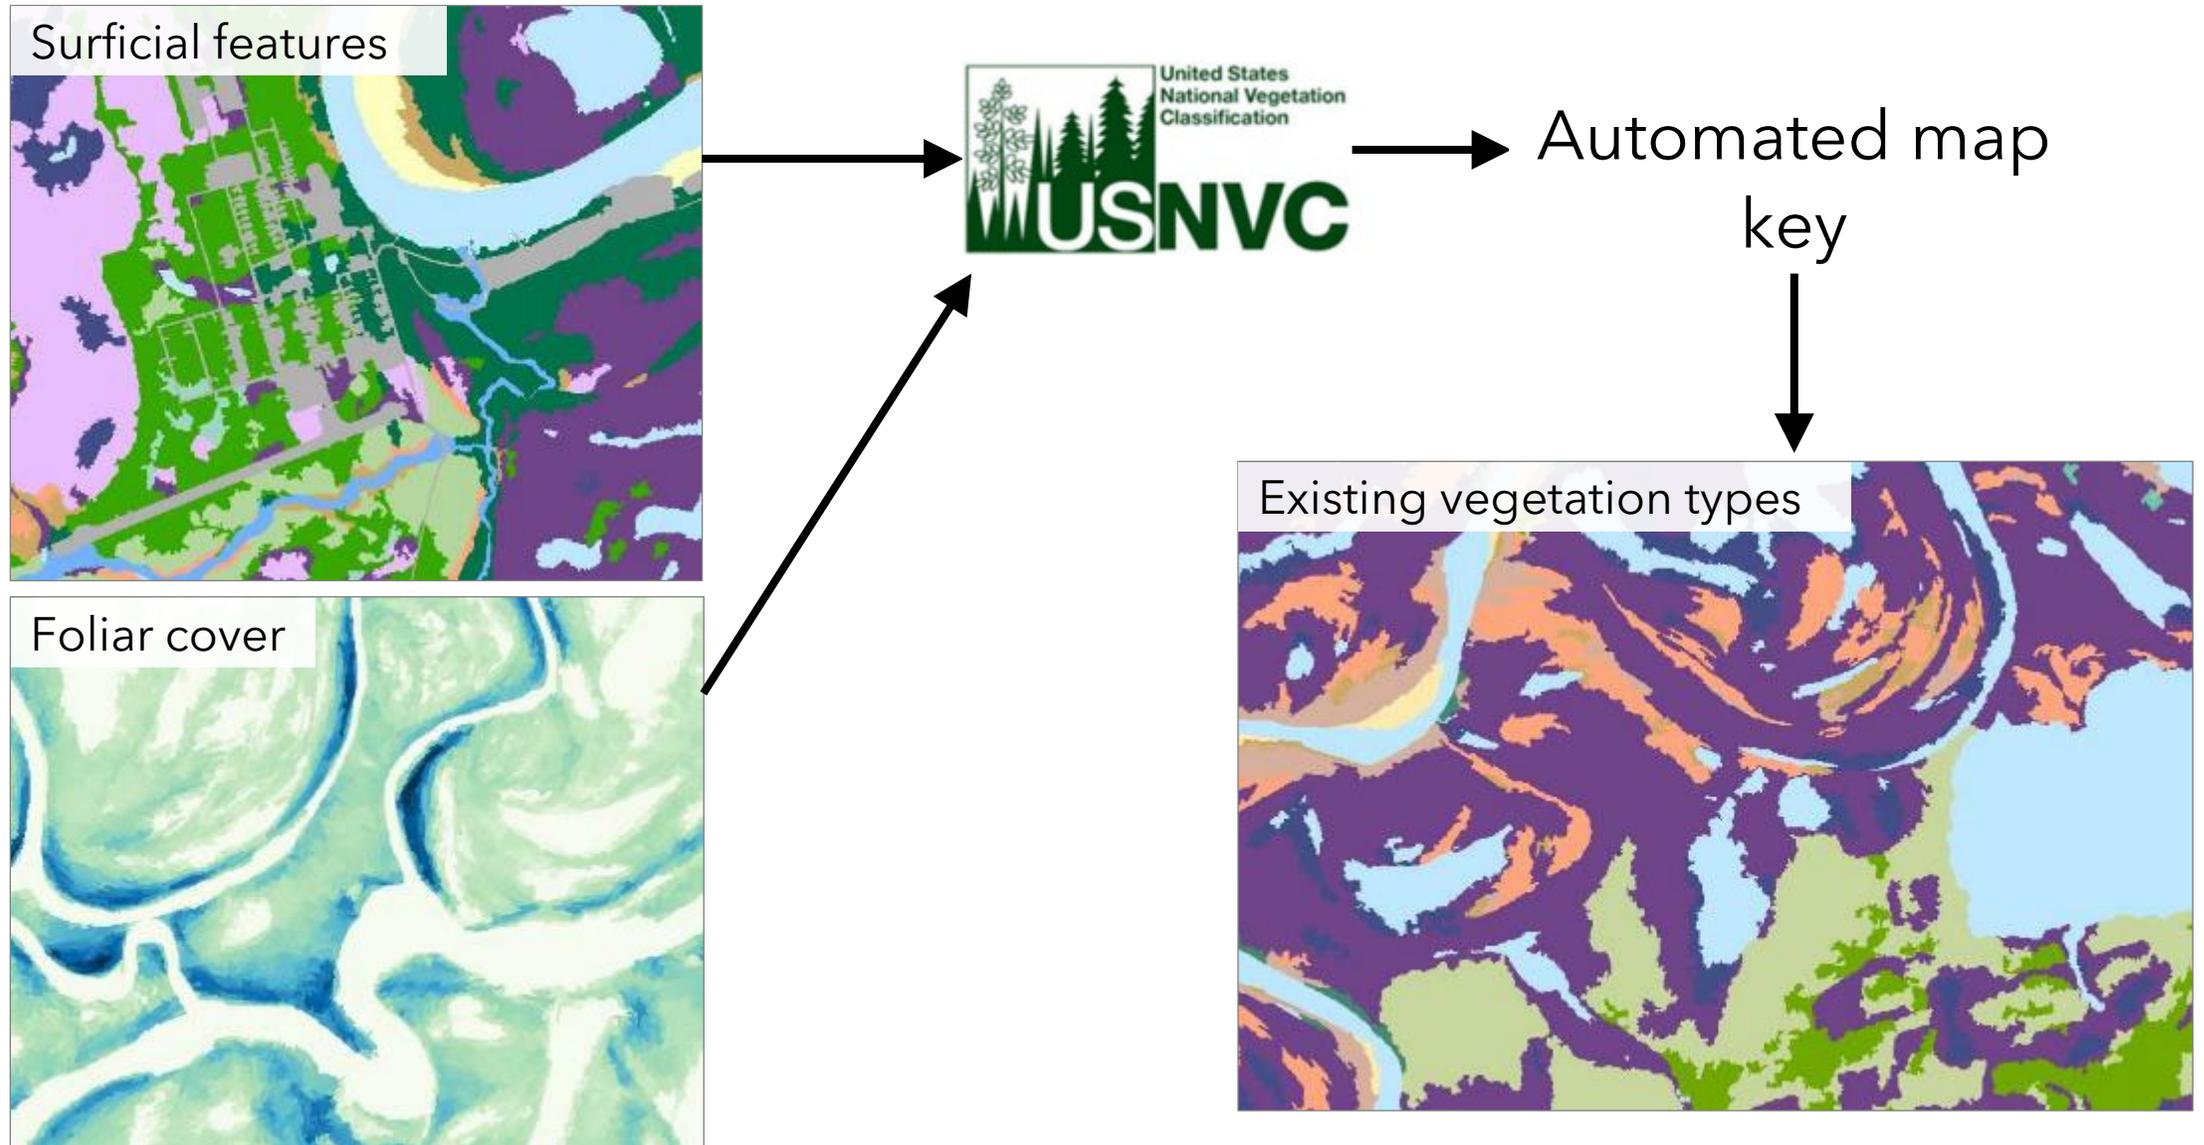

# Interpreting predictive $R^2$ and RMSE

- Predictive  $R^2$  is the  $R^2$  of the model predictions, not of the model
- Calculated from a simple OLS model for observed values as a function of predicted values where the intercept is 0 and the slope coefficient is 1.
- The amount of "generalization".
- RMSE is in the same units as the dependent variable.
- The "discriminatory" power of the model.

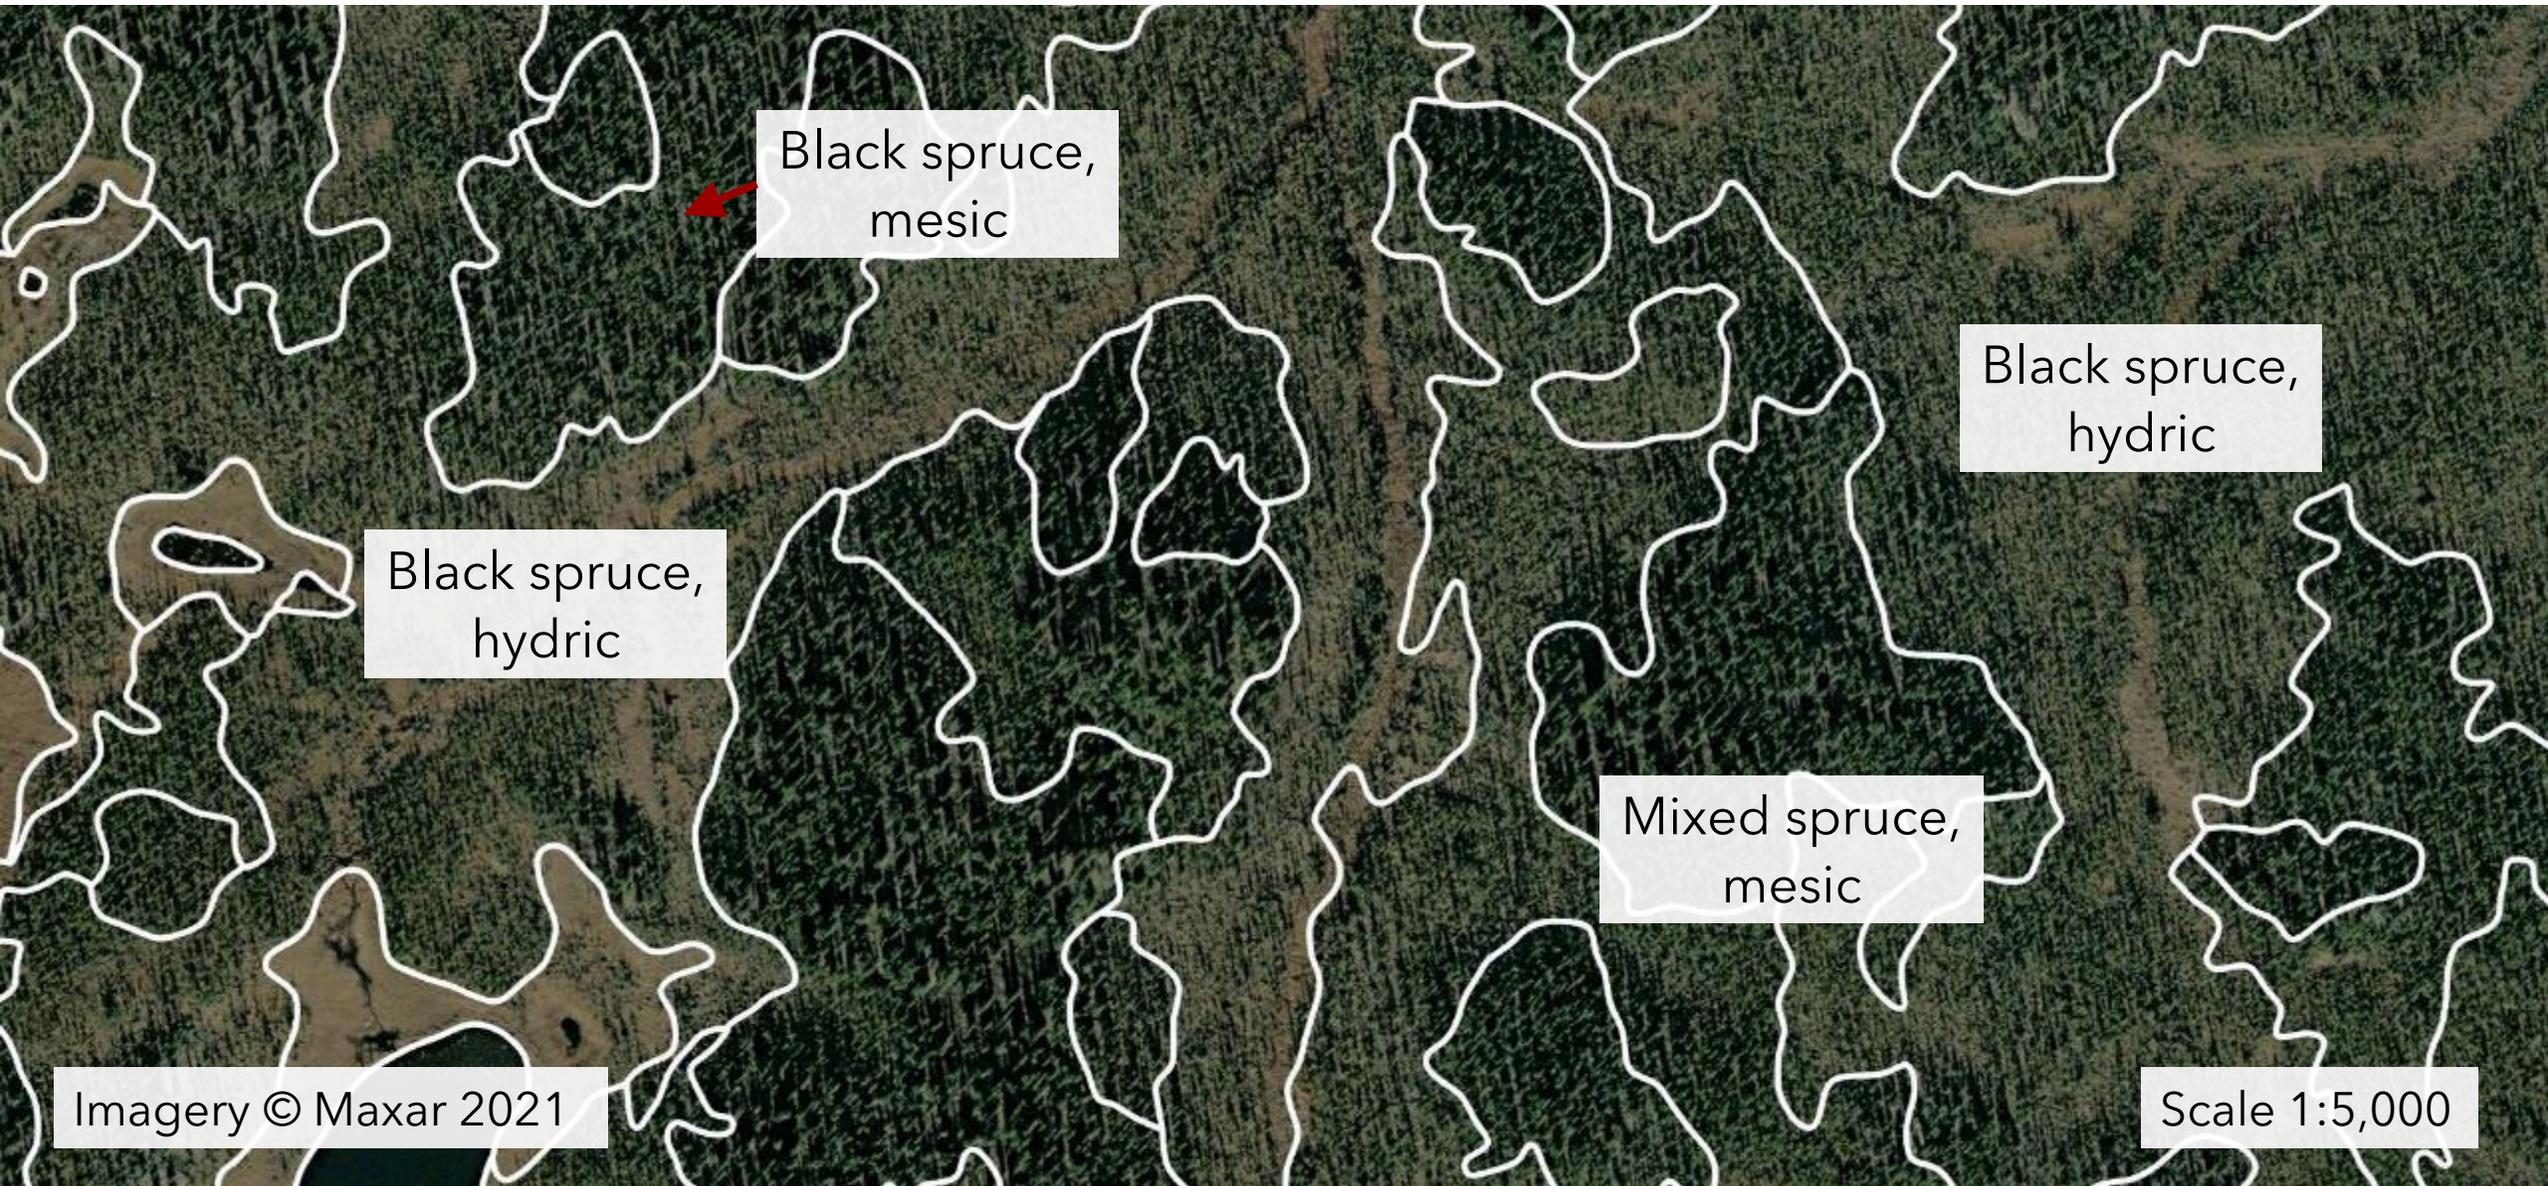

# Map wetland vegetation types using programmatic key

# Map wetland vegetation types using programmatic key

# Separate similar types using component indicators

Black spruce,  
mesic

Black spruce,  
hydric

Black spruce,  
hydric

Mixed spruce,  
mesic

Should it be mapped as wetland? It depends...

Should it be mapped as wetland? It depends...

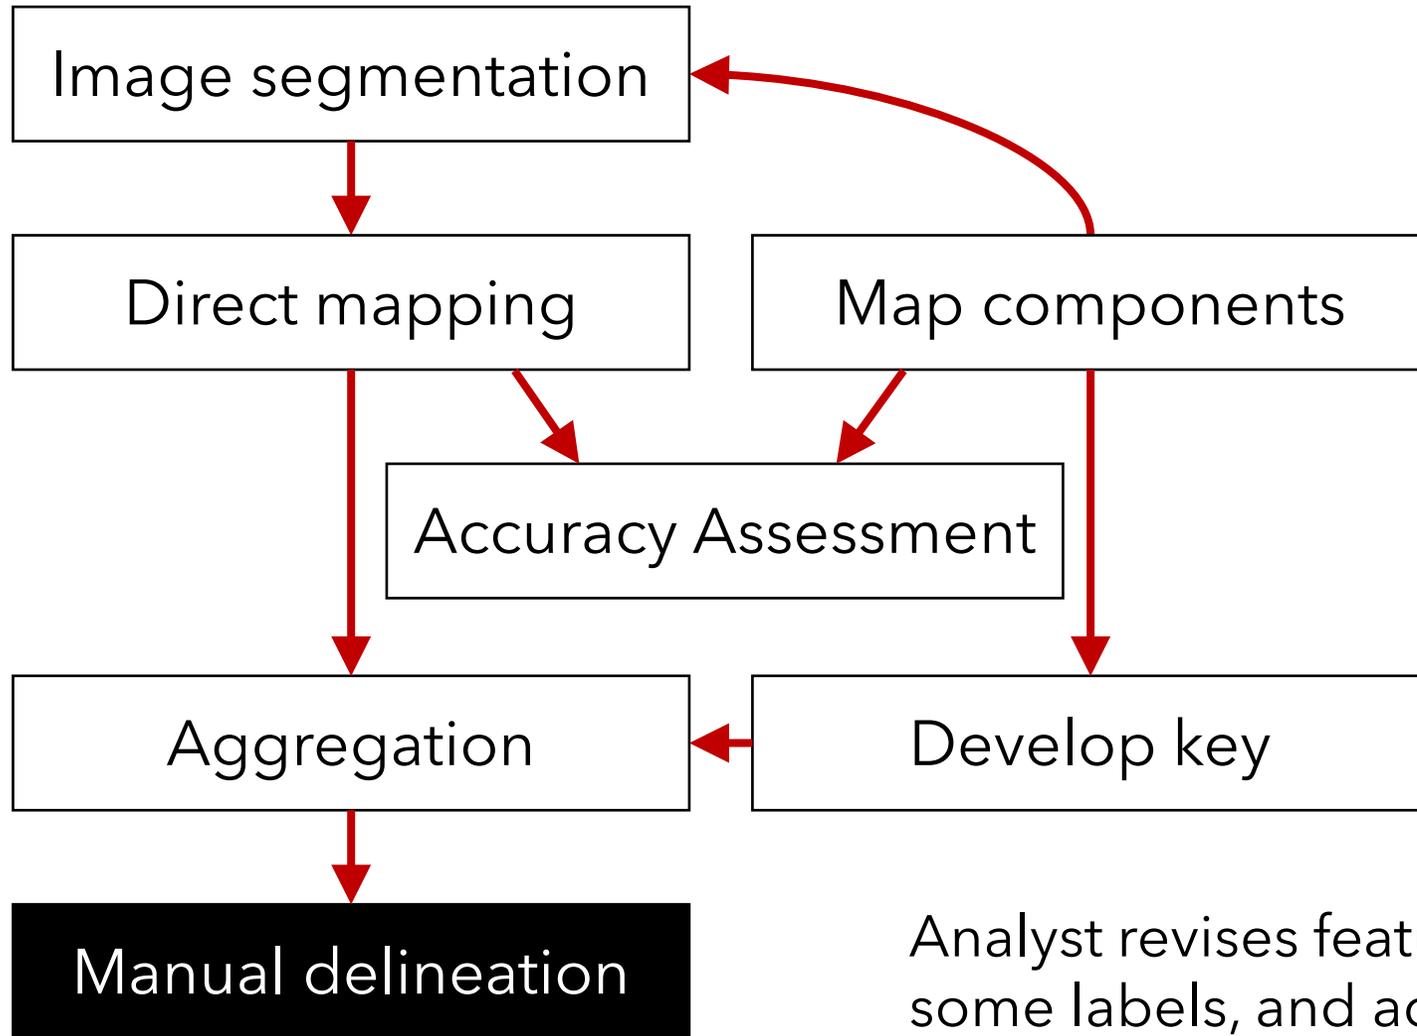

1-parameter: **Yes...** but is *Eriophorum vaginatum* reliable in this context?

Should it be mapped as wetland? It depends...

3-parameter: **No.**

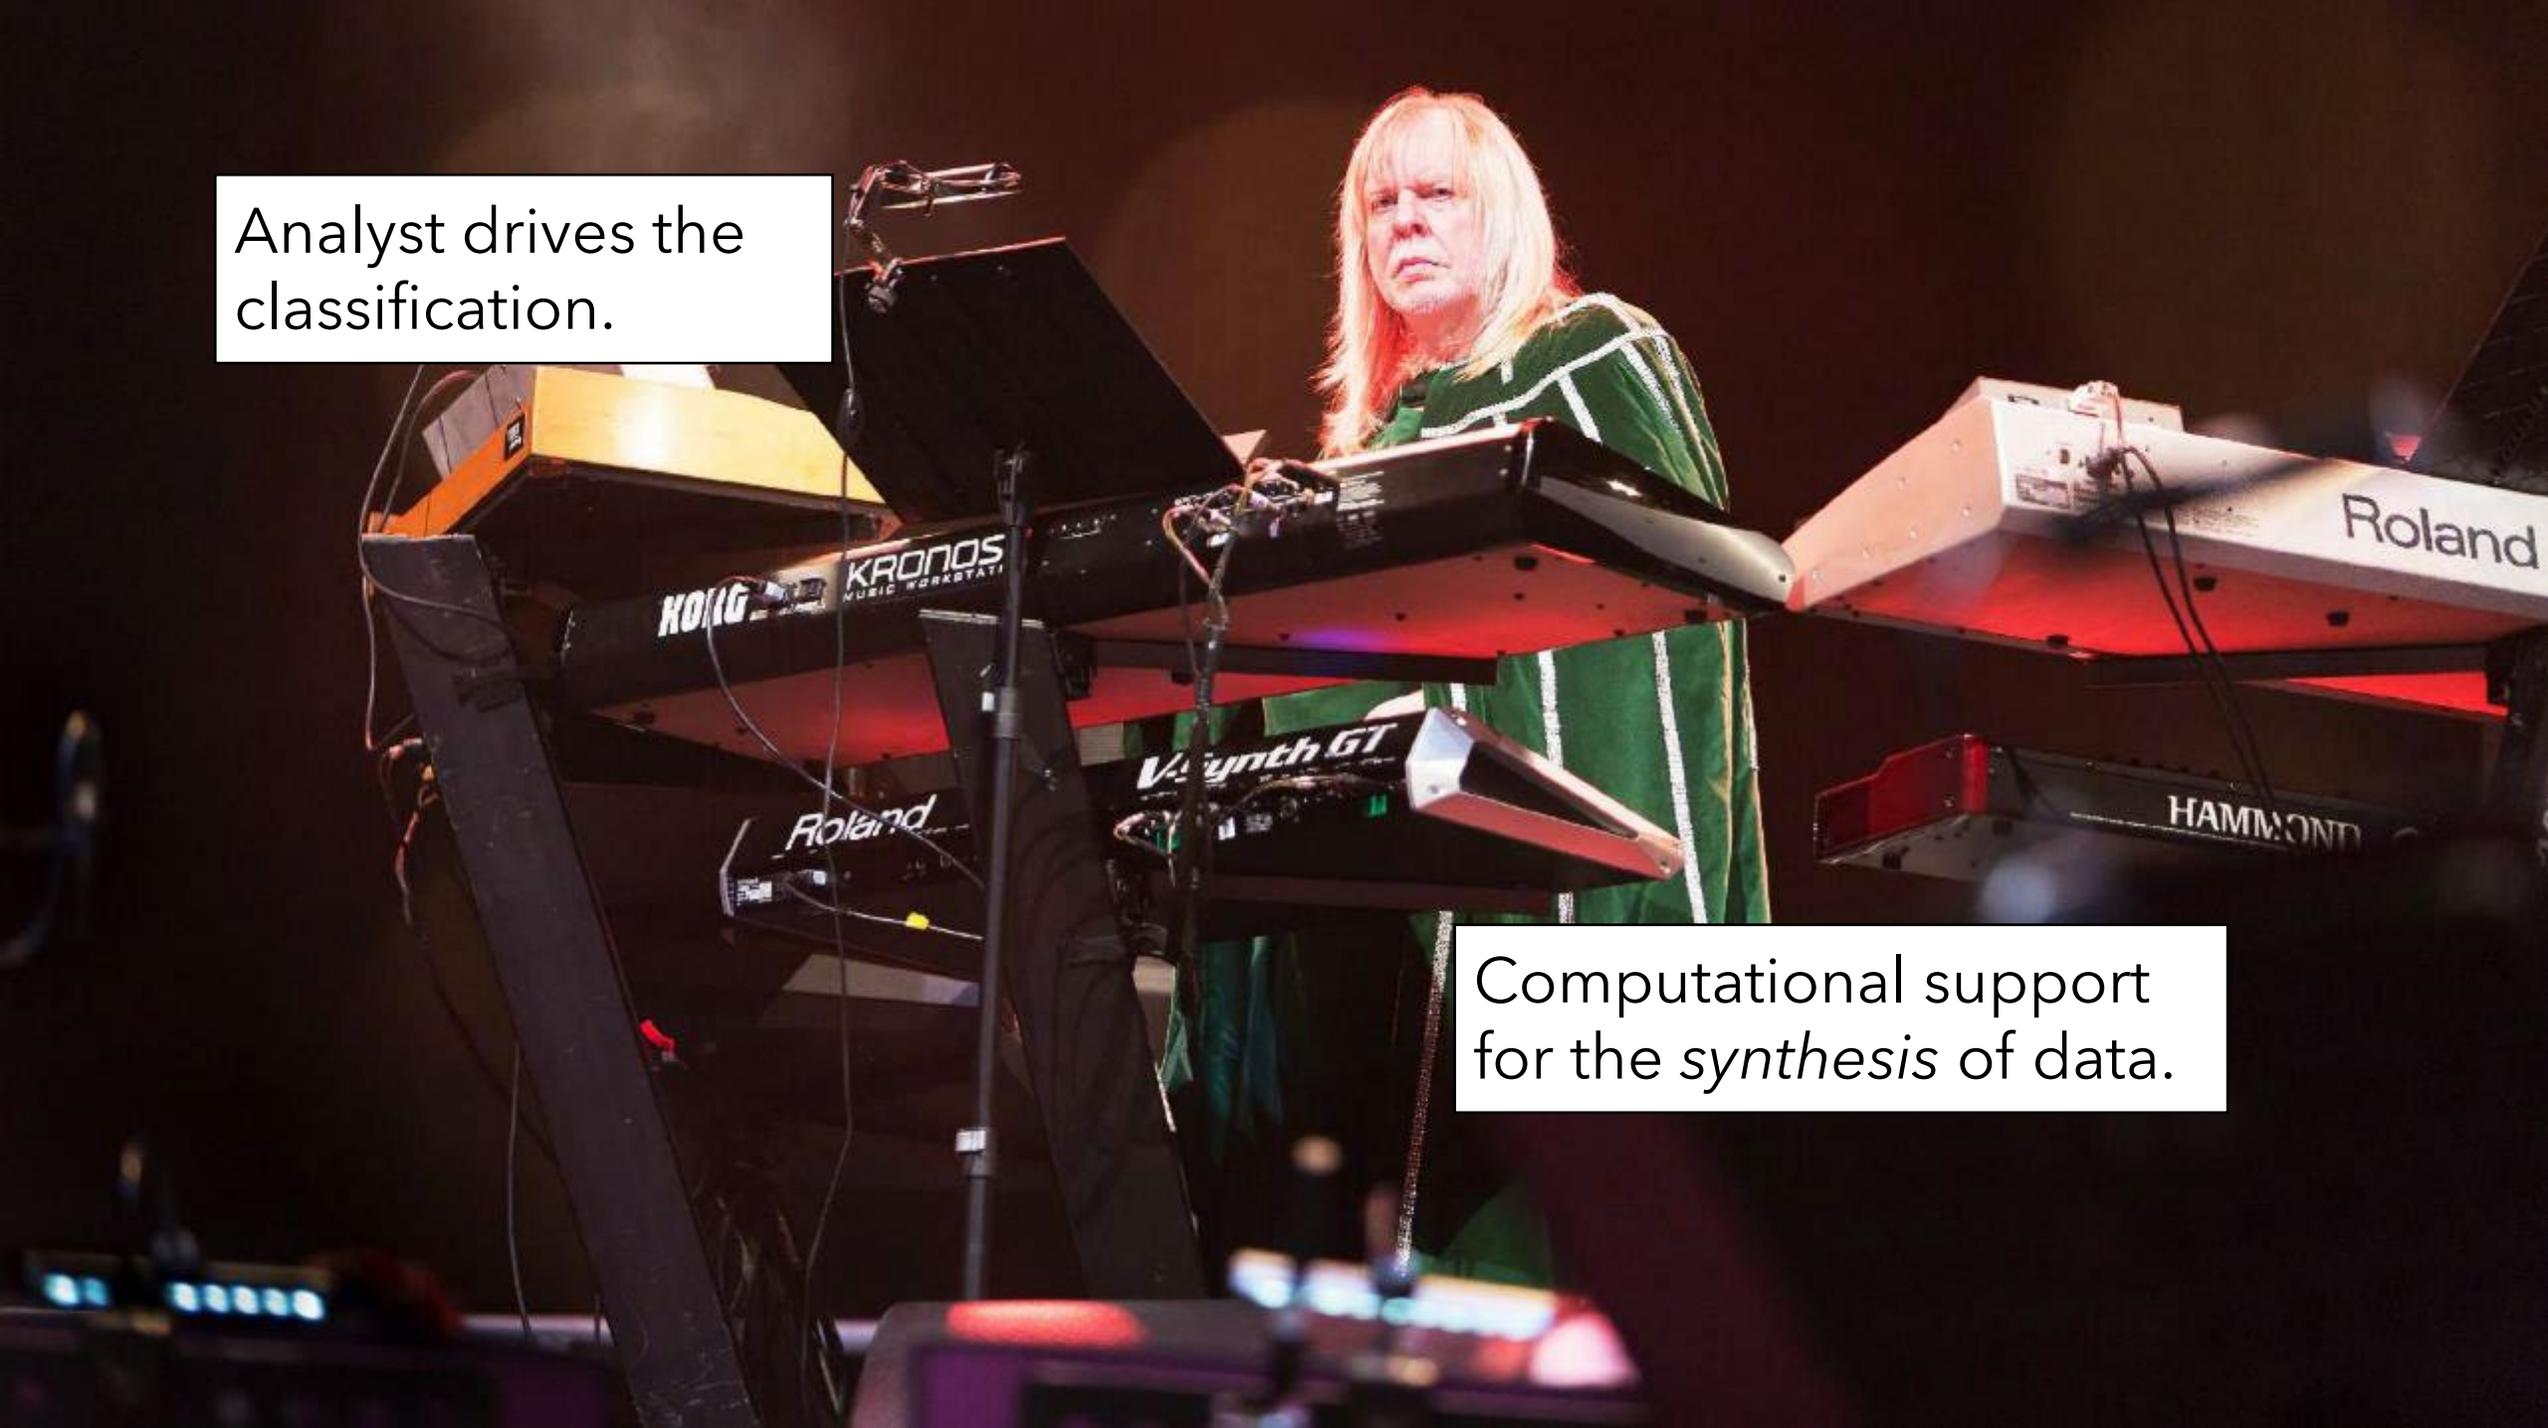

1. Absence of hydric soils.
2. Not seasonally or partially inundated.

# Semi-automated workflow

Workflow is scripted for repeatability.

Analyst revises feature polygons, corrects some labels, and adds non-modeled features.

A woman with long blonde hair is performing on stage, playing a multi-tiered keyboard setup. The setup includes a yellow Nord keyboard on top, a black Korg Kronos Music Workstation in the middle, and a Roland V-Synth GT below it. To the right, a white Hammond keyboard is visible. The woman is wearing a green jacket with white stripes. The background is dark with some stage lighting.

Analyst drives the classification.

Computational support for the *synthesis* of data.

# Conclusion

*Automated methods offer:*

1. Statistically robust accuracy assessment.
2. Consistency at large extents.
3. Integration of multi-parameter wetland attributes.
4. Repeatability for updates and alterations.
5. Cost efficiency for large regions.

Combined with a knowledgeable analyst, workflow can combine benefits of *automated* and *manual* methods.

Presented as an idea rather than a true proof of concept.
